Release information

For information on the change history and known issues for this release, see the Release notes in the A64 ISA XML for A-profile architecture (2026-09).

Non-Confidential Proprietary Notice

This document is protected by copyright and other related rights and the use or implementation of the information contained in this document may be protected by one or more patents or pending patent applications. No part of this document may be reproduced in any form by any means without the express prior written permission of Arm Limited ("Arm"). **No license, express or implied, by estoppel or otherwise to any intellectual property rights is granted by this document unless specifically stated.**

Your access to the information in this document is conditional upon your acceptance that you will not use or permit others to use the information for the purposes of determining whether the subject matter of this document infringes any third party patents.

The content of this document is informational only. Any solutions presented herein are subject to changing conditions, information, scope, and data. This document was produced using reasonable efforts based on information available as of the date of issue of this document. The scope of information in this document may exceed that which Arm is required to provide, and such additional information is merely intended to further assist the recipient and does not represent Arm's view of the scope of its obligations. You acknowledge and agree that you possess the necessary expertise in system security and functional safety and that you shall be solely responsible for compliance with all legal, regulatory, safety and security related requirements concerning your products, notwithstanding any information or support that may be provided by Arm herein. In addition, you are responsible for any applications which are used in conjunction with any Arm technology described in this document, and to minimize risks, adequate design and operating safeguards should be provided for by you.

This document may include technical inaccuracies or typographical errors. THIS DOCUMENT IS PROVIDED "AS IS". ARM PROVIDES NO REPRESENTATIONS AND NO WARRANTIES, EXPRESS, IMPLIED OR STATUTORY, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY, SATISFACTORY QUALITY, NON-INFRINGEMENT OR FITNESS FOR A PARTICULAR PURPOSE WITH RESPECT TO THE DOCUMENT. For the avoidance of doubt, Arm makes no representation with respect to, and has undertaken no analysis to identify or understand the scope and content of, any patents, copyrights, trade secrets, trademarks, or other rights.

TO THE EXTENT NOT PROHIBITED BY LAW, IN NO EVENT WILL ARM BE LIABLE FOR ANY DAMAGES, INCLUDING WITHOUT LIMITATION ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, PUNITIVE, OR CONSEQUENTIAL DAMAGES, HOWEVER CAUSED AND REGARDLESS OF THE THEORY OF LIABILITY, ARISING OUT OF ANY USE OF THIS DOCUMENT, EVEN IF ARM HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Reference by Arm to any third party's products or services within this document is not an express or implied approval or endorsement of the use thereof.

This document consists solely of commercial items. You shall be responsible for ensuring that any permitted use, duplication, or disclosure of this document complies fully with any relevant export laws and regulations to assure that this document or any portion thereof is not exported, directly or indirectly, in violation of such export laws. Use of the word "partner" in reference to Arm's customers is not intended to create or refer to any partnership relationship with any other company. Arm may make changes to this document at any time and without notice.

This document may be translated into other languages for convenience, and you agree that if there is any conflict between the English version of this document and any translation, the terms of the English version of this document shall prevail.

The validity, construction and performance of this notice shall be governed by English Law.

PRE-20349

8 March 2024

Confidentiality Status

This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by Arm and the party that Arm delivered this document to.

Product Status

The information relating to the A-profile Architecture in this document is at Beta quality. Beta quality means that all major features of the specification are described, but some details might be missing.

Progressive Terminology Commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

Previous issues of this document included terms that can be offensive. We have replaced these terms.

If you find offensive terms in this document, please contact terms@arm.com.

Feedback on this document

If you have any comments or queries about this document, create a ticket at support.arm.com/support-cases.

As part of the ticket, include:

- The title, *Arm® A64 Instruction Set for A-profile architecture*.
- The number, 111182 (ID102025).
- The section name to which your comments refer.
- The page number(s) to which your comments refer.
- The rule identifier(s) to which your comments refer if applicable.
- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

A64 -- Base Instructions (alphabetic order)

ABS: Absolute value.

ADC: Add with carry.

ADCS: Add with carry, setting flags.

ADD (extended register): Add extended and scaled register.

ADD (immediate): Add immediate value.

ADD (shifted register): Add optionally-shifted register.

ADDG: Add with tag.

ADDPT: Add checked pointer.

ADDS (extended register): Add extended and scaled register, setting flags.

ADDS (immediate): Add immediate value, setting flags.

ADDS (shifted register): Add optionally-shifted register, setting flags.

ADR: Form PC-relative address.

ADRP: Form PC-relative address to 4KB page.

AND (immediate): Bitwise AND (immediate).

AND (shifted register): Bitwise AND (shifted register).

ANDS (immediate): Bitwise AND (immediate), setting flags.

ANDS (shifted register): Bitwise AND (shifted register), setting flags.

APAS: Associate physical address space: an alias of SYS.

ASR (immediate): Arithmetic shift right (immediate): an alias of SBFM.

ASR (register): Arithmetic shift right (register): an alias of ASRV.

ASRV: Arithmetic shift right variable.

AT: Address translate: an alias of SYS.

AUTDA, AUTDZA: Authenticate data address, using key A.

AUTDB, AUTDZB: Authenticate data address, using key B.

AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA: Authenticate instruction address, using key A.

AUTIA171615: Authenticate instruction address, using key A.

AUTIASPPC: Authenticate return address using key A, using an immediate offset.

AUTIASPPCR: Authenticate return address using key A, using a register.

AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB: Authenticate instruction address, using key B.

AUTIB171615: Authenticate instruction address, using key B.

AUTIBSPPC: Authenticate return address using key B, using an immediate offset.

AUTIBSPPCR: Authenticate return address using key B, using a register.

AXFLAG: Convert floating-point condition flags from Arm to external format.

B: Branch.

B.cond: Branch conditionally.

BC.cond: Branch consistent conditionally.

BFC: Bitfield clear: an alias of BFM.

BFI: Bitfield insert: an alias of BFM.

BFM: Bitfield move.

BFXIL: Bitfield extract and insert at low end: an alias of BFM.

BIC (shifted register): Bitwise bit clear (shifted register).

BICS (shifted register): Bitwise bit clear (shifted register), setting flags.

BL: Branch with link.

BLR: Branch with link to register.

BLRAA, BLRAAZ, BLRAB, BLRABZ: Branch with link to register, with pointer authentication.

BR: Branch to register.

BRAA, BRAAZ, BRAB, BRABZ: Branch to register, with pointer authentication.

BRB: Branch record buffer: an alias of SYS.

BRK: Breakpoint instruction.

BTI: Branch target identification.

CAS, CASA, CASAL, CASL: Compare and swap word or doubleword in memory.

CASB, CASAB, CASALB, CASLB: Compare and swap byte in memory.

CASH, CASAH, CASALH, CASLH: Compare and swap halfword in memory.

CASP, CASPA, CASPAL, CASPL: Compare and swap pair of words or doublewords in memory.

CASPT, CASPAT, CASPALT, CASPLT: Compare and swap pair unprivileged.

CAST, CASAT, CASALT, CASLT: Compare and swap unprivileged.

CB<cc> (immediate): Compare register with immediate and branch.

CB<cc> (register): Compare registers and branch.

CBB<cc>: Compare bytes and branch.

CBBLE: Compare signed less than or equal to bytes and branch: an alias of CBB<cc>.

CBBLO: Compare unsigned lower than bytes and branch: an alias of CBB<cc>.

CBBLS: Compare unsigned lower than or same as bytes and branch: an alias of CBB<cc>.

CBBLT: Compare signed less than bytes and branch: an alias of CBB<cc>.

CBGE (immediate): Compare signed greater than or equal to immediate and branch: an alias of CB<cc> (immediate).

CBH<cc>: Compare halfwords and branch.

CBHLE: Compare signed less than or equal to halfwords and branch: an alias of CBH<cc>.

CBHLO: Compare unsigned lower than halfwords and branch: an alias of CBH<cc>.

CBHLS: Compare unsigned lower than or same as halfwords and branch: an alias of CBH<cc>.

CBHLT: Compare signed less than halfwords and branch: an alias of CBH<cc>.

CBHS (immediate): Compare unsigned higher than or same as immediate and branch: an alias of CB<cc> (immediate).

CBLE (immediate): Compare signed less than or equal to immediate and branch: an alias of CB<cc> (immediate).

CBLE (register): Compare signed less than or equal to register and branch: an alias of CB<cc> (register).

CBLO (register): Compare unsigned lower than register and branch: an alias of CB<cc> (register).

CBLS (immediate): Compare unsigned lower than or same as immediate and branch: an alias of CB<cc> (immediate).

CBLS (register): Compare unsigned lower than or same as register and branch: an alias of CB<cc> (register).

CBLT (register): Compare signed less than register and branch: an alias of CB<cc> (register).

CBNZ: Compare and branch on nonzero.

CBZ: Compare and branch on zero.

CCMN (immediate): Conditional compare negative (immediate).

CCMN (register): Conditional compare negative (register).

CCMP (immediate): Conditional compare (immediate).

CCMP (register): Conditional compare (register).

CFINV: Invert carry flag.

CFLT<cc> (immediate): Compare register with immediate and fault.

CFLT<cc> (register): Compare registers and fault.

CFLTGE (immediate): Compare signed greater than or equal to immediate and fault: an alias of CFLT<cc> (immediate).

CFLTHS (immediate): Compare unsigned higher than or same as immediate and fault: an alias of CFLT<cc> (immediate).

CFLTLE (immediate): Compare signed less than or equal to immediate and fault: an alias of CFLT<cc> (immediate).

CFLTLE (register): Compare registers and fault if less than or equal: an alias of CFLT<cc> (register).

CFLTLO (register): Compare registers and fault if lower: an alias of CFLT<cc> (register).

CFLTLS (immediate): Compare unsigned lower than or same as immediate and fault: an alias of CFLT<cc> (immediate).

CFLTLS (register): Compare registers and fault if lower than or same: an alias of CFLT<cc> (register).

CFLTLT (register): Compare registers and fault if less than: an alias of CFLT<cc> (register).

CFLTNZ: Compare and fault on nonzero: an alias of CFLT<cc> (immediate).

CFLTZ: Compare and fault on zero: an alias of CFLT<cc> (immediate).

CFP: Control flow prediction restriction by context: an alias of SYS.

CHKFEAT: Check feature status.

CINC: Conditional increment: an alias of CSINC.

CINV: Conditional invert: an alias of CSINV.

CLRBHB: Clear branch history.

CLREX: Clear exclusive.

CLS: Count leading sign bits.

CLZ: Count leading zeros.

CMN (extended register): Compare negative (extended register): an alias of ADDS (extended register).

CMN (immediate): Compare negative (immediate): an alias of ADDS (immediate).

CMN (shifted register): Compare negative (shifted register): an alias of ADDS (shifted register).

CMP (extended register): Compare (extended register): an alias of SUBS (extended register).

CMP (immediate): Compare (immediate): an alias of SUBS (immediate).

CMP (shifted register): Compare (shifted register): an alias of SUBS (shifted register).

CMPP: Compare with tag: an alias of SUBPS.

CNEG: Conditional negate: an alias of CSNEG.

CNT: Count bits.

COSP: Clear other speculative prediction restriction by context: an alias of SYS.

CPP: Cache prefetch prediction restriction by context: an alias of SYS.

CPYFP, CPYFM, CPYFE: Memory copy forward-only.

CPYFPN, CPYFMN, CPYFEN: Memory copy forward-only, reads and writes non-temporal.

CPYFPRN, CPYFMRN, CPYFERN: Memory copy forward-only, reads non-temporal.

CPYFPRT, CPYFMRT, CPYFERT: Memory copy forward-only, reads unprivileged.

CPYFPRTN, CPYFMRTN, CPYFERTN: Memory copy forward-only, reads unprivileged, reads and writes non-temporal.

CPYFPRTRN, CPYFMRTRN, CPYFERTRN: Memory copy forward-only, reads unprivileged and non-temporal.

CPYFPRTWN, CPYFMRTWN, CPYFERTWN: Memory copy forward-only, reads unprivileged, writes non-temporal.

CPYFPT, CPYFMT, CPYFET: Memory copy forward-only, reads and writes unprivileged.

CPYFPTN, CPYFMTN, CPYFETN: Memory copy forward-only, reads and writes unprivileged and non-temporal.

CPYFPTRN, CPYFMTRN, CPYFETRN: Memory copy forward-only, reads and writes unprivileged, reads non-temporal.

CPYFPTWN, CPYFMTWN, CPYFETWN: Memory copy forward-only, reads and writes unprivileged, writes non-temporal.

CPYFPWN, CPYFMWN, CPYFEWN: Memory copy forward-only, writes non-temporal.

CPYFPWT, CPYFMWT, CPYFEWT: Memory copy forward-only, writes unprivileged.

CPYFPWTN, CPYFMWTN, CPYFEWTN: Memory copy forward-only, writes unprivileged, reads and writes non-temporal.

CPYFPWTRN, CPYFMWTRN, CPYFEWTRN: Memory copy forward-only, writes unprivileged, reads non-temporal.

CPYFPWTWN, CPYFMWTWN, CPYFEWTWN: Memory copy forward-only, writes unprivileged and non-temporal.

CPYP, CPYM, CPYE: Memory copy.

CPYPN, CPYMN, CPYEN: Memory copy, reads and writes non-temporal.

CPYPRN, CPYMRN, CPYERN: Memory copy, reads non-temporal.

CPYPRT, CPYMRT, CPYERT: Memory copy, reads unprivileged.

CPYPRTN, CPYMRTN, CPYERTN: Memory copy, reads unprivileged, reads and writes non-temporal.

CPYPRTRN, CPYMRTRN, CPYERTRN: Memory copy, reads unprivileged and non-temporal.

CPYPRTWN, CPYMRTWN, CPYERTWN: Memory copy, reads unprivileged, writes non-temporal.

CPYPT, CPYMT, CPYET: Memory copy, reads and writes unprivileged.

CPYPTN, CPYMTN, CPYETN: Memory copy, reads and writes unprivileged and non-temporal.

CPYPTRN, CPYMTRN, CPYETRN: Memory copy, reads and writes unprivileged, reads non-temporal.

CPYPTWN, CPYMTWN, CPYETWN: Memory copy, reads and writes unprivileged, writes non-temporal.

CPYPWN, CPYMWN, CPYEWN: Memory copy, writes non-temporal.

CPYPWT, CPYMWT, CPYEWT: Memory copy, writes unprivileged.

CPYPWTN, CPYMWTN, CPYEWTN: Memory copy, writes unprivileged, reads and writes non-temporal.

CPYPWTRN, CPYMWTRN, CPYEWTRN: Memory copy, writes unprivileged, reads non-temporal.

CPYPWTWN, CPYMWTWN, CPYEWTWN: Memory copy, writes unprivileged and non-temporal.

CRC32B, CRC32H, CRC32W, CRC32X: CRC32 checksum.

CRC32CB, CRC32CH, CRC32CW, CRC32CX: CRC32C checksum.

CSDB: Consumption of speculative data barrier.

CSEL: Conditional select.

CSET: Conditional set: an alias of CSINC.

CSETM: Conditional set mask: an alias of CSINV.

CSINC: Conditional select increment.

CSINV: Conditional select invert.

CSNEG: Conditional select negation.

CTZ: Count trailing zeros.

DC: Data cache operation: an alias of SYS.

DCPS1: Debug change PE state to EL1.

DCPS2: Debug change PE state to EL2.

DCPS3: Debug change PE state to EL3.

DGH: Data gathering hint.

DMB: Data memory barrier.

DRPS: Debug restore PE state.

DSB: Data synchronization barrier.

DVP: Data value prediction restriction by context: an alias of SYS.

EON (shifted register): Bitwise exclusive-OR NOT (shifted register).

EOR (immediate): Bitwise exclusive-OR (immediate).

EOR (shifted register): Bitwise exclusive-OR (shifted register).

ERET: Exception return.

ERETAA, ERETAB: Exception return, with pointer authentication.

ESB: Error synchronization barrier.

EXTR: Extract register.

FLT.cond: Conditional fault.

GCSB: Guarded Control Stack barrier.

GCSPOPCX: Guarded Control Stack pop and compare exception return record: an alias of SYS.

GCSPOPM: Guarded Control Stack pop: an alias of SYSL.

GCSPOPX: Guarded Control Stack pop exception return record: an alias of SYS.

GCSPUSHM: Guarded Control Stack push: an alias of SYS.

GCSPUSHX: Guarded Control Stack push exception return record: an alias of SYS.

GCSSS1: Guarded Control Stack switch stack 1: an alias of SYS.

GCSSS2: Guarded Control Stack switch stack 2: an alias of SYSL.

GCSSTR: Guarded Control Stack store register.

GCSSTTR: Guarded Control Stack store register (unprivileged).

GIC: Generic Interrupt Controller: an alias of SYS.

GICR: Generic Interrupt Controller with result: an alias of SYSL.

GMI: Tag mask insert.

GSB: Generic Interrupt Controller synchronization barrier: an alias of SYS.

HINT: Hint instruction.

HINTE: Hint instruction (extended).

HLT: Halt instruction.

HVC: Hypervisor call.

IC: Instruction cache operation: an alias of SYS.

IRG: Insert random tag.

ISB: Instruction synchronization barrier.

LD64B: Single-copy atomic 64-byte load.

LDA64B: Single-copy atomic 64-byte load-acquire.

LDADD, LDADDA, LDADDAL, LDADDL: Atomic add on word or doubleword.

LDADDB, LDADDAB, LDADDALB, LDADDLB: Atomic add on byte.

LDADDH, LDADDAH, LDADDALH, LDADDLH: Atomic add on halfword.

LDAP: Load-acquire pair of registers.

LDAPP: Load-acquire RCpc pair of registers.

LDAPR: Load-acquire RCpc register.

LDAPRB: Load-acquire RCpc register byte.

LDAPRH: Load-acquire RCpc register halfword.

LDAPUR: Load-acquire RCpc register (unscaled).

LDAPURB: Load-acquire RCpc register byte (unscaled).

LDAPURH: Load-acquire RCpc register halfword (unscaled).

LDAPURSB: Load-acquire RCpc register signed byte (unscaled).

LDAPURSH: Load-acquire RCpc register signed halfword (unscaled).

LDAPURSW: Load-acquire RCpc register signed word (unscaled).

LDAR: Load-acquire register.

LDARB: Load-acquire register byte.

LDARH: Load-acquire register halfword.

LDATXR: Load-acquire unprivileged exclusive register.

LDAXP: Load-acquire exclusive pair of registers.

LDAXR: Load-acquire exclusive register.

LDAXRB: Load-acquire exclusive register byte.

LDAXRH: Load-acquire exclusive register halfword.

LDCLR, LDCLRA, LDCLRAL, LDCLRL: Atomic bit clear on word or doubleword.

LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB: Atomic bit clear on byte.

LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH: Atomic bit clear on halfword.

LDCLRP, LDCLRPA, LDCLRPAL, LDCLRPL: Atomic bit clear on quadword.

LDEOR, LDEORA, LDEORAL, LDEORL: Atomic exclusive-OR on word or doubleword.

LDEORB, LDEORAB, LDEORALB, LDEORLB: Atomic exclusive-OR on byte.

LDEORH, LDEORAH, LDEORALH, LDEORLH: Atomic exclusive-OR on halfword.

LDG: Load Allocation Tag.

LDGM: Load tag multiple.

LDIAPP: Load-Acquire RCpc ordered pair of registers.

LDLAR: Load LOAcquire register.

LDLARB: Load LOAcquire register byte.

LDLARH: Load LOAcquire register halfword.

LDNP: Load pair of registers, with non-temporal hint.

LDP: Load pair of registers.

LDPSW: Load pair of registers signed word.

LDR (immediate): Load register (immediate).

LDR (literal): Load register (literal).

LDR (register): Load register (register).

LDRAA, LDRAB: Load register, with pointer authentication.

LDRB (immediate): Load register byte (immediate).

LDRB (register): Load register byte (register).

LDRH (immediate): Load register halfword (immediate).

LDRH (register): Load register halfword (register).

LDRSB (immediate): Load register signed byte (immediate).

LDRSB (register): Load register signed byte (register).

LDRSH (immediate): Load register signed halfword (immediate).

LDRSH (register): Load register signed halfword (register).

LDRSW (immediate): Load register signed word (immediate).

LDRSW (literal): Load register signed word (literal).

LDRSW (register): Load register signed word (register).

LDSET, LDSETA, LDSETAL, LDSETL: Atomic bit set on word or doubleword.

LDSETB, LDSETAB, LDSETALB, LDSETLB: Atomic bit set on byte.

LDSETH, LDSETAH, LDSETALH, LDSETLH: Atomic bit set on halfword.

LDSETP, LDSETPA, LDSETPAL, LDSETPL: Atomic bit set on quadword.

LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL: Atomic signed maximum on word or doubleword.

LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB: Atomic signed maximum on byte.

LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH: Atomic signed maximum on halfword.

LDSMIN, LDSMINA, LDSMINAL, LDSMINL: Atomic signed minimum on word or doubleword.

LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB: Atomic signed minimum on byte.

LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH: Atomic signed minimum on halfword.

LDTADD, LDTADDA, LDTADDAL, LDTADDL: Atomic add unprivileged.

LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL: Atomic bit clear unprivileged.

LDTNP: Load unprivileged pair of registers, with non-temporal hint.

LDTP: Load unprivileged pair of registers.

LDTR: Load register (unprivileged).

LDTRB: Load register byte (unprivileged).

LDTRH: Load register halfword (unprivileged).

LDTRSB: Load register signed byte (unprivileged).

LDTRSH: Load register signed halfword (unprivileged).

LDTRSW: Load register signed word (unprivileged).

LDTSET, LDTSETA, LDTSETAL, LDTSETL: Atomic bit set unprivileged.

LDTXR: Load unprivileged exclusive register.

LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL: Atomic unsigned maximum on word or doubleword.

LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB: Atomic unsigned maximum on byte.

LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH: Atomic unsigned maximum on halfword.

LDUMIN, LDUMINA, LDUMINAL, LDUMINL: Atomic unsigned minimum on word or doubleword.

LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB: Atomic unsigned minimum on byte.

LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH: Atomic unsigned minimum on halfword.

LDUR: Load register (unscaled).

LDURB: Load register byte (unscaled).

LDURH: Load register halfword (unscaled).

LDURSB: Load register signed byte (unscaled).

LDURSH: Load register signed halfword (unscaled).

LDURSW: Load register signed word (unscaled).

LDXP: Load exclusive pair of registers.

LDXR: Load exclusive register.

LDXRB: Load exclusive register byte.

LDXRH: Load exclusive register halfword.

LSL (immediate): Logical shift left (immediate): an alias of UBFM.

LSL (register): Logical shift left (register): an alias of LSLV.

LSLV: Logical shift left variable.

LSR (immediate): Logical shift right (immediate): an alias of UBFM.

LSR (register): Logical shift right (register): an alias of LSRV.

LSRV: Logical shift right variable.

MADD: Multiply-add.

MADDPT: Multiply-add checked pointer.

MNEG: Multiply-negate: an alias of MSUB.

MOV (bitmask immediate): Move bitmask immediate value: an alias of ORR (immediate).

MOV (inverted wide immediate): Move inverted wide immediate value: an alias of MOVN.

MOV (register): Move register value: an alias of ORR (shifted register).

MOV (to/from SP): Move register value to or from SP: an alias of ADD (immediate).

MOV (wide immediate): Move wide immediate value: an alias of MOVZ.

MOVK: Move wide with keep.

MOVN: Move wide with NOT.

MOVZ: Move wide with zero.

MRRS: Move System register to two adjacent general-purpose registers.

MRS: Move System register to general-purpose register.

MSR (immediate): Move immediate value to special register.

MSR (register): Move general-purpose register to System register.

MSRR: Move two adjacent general-purpose registers to System register.

MSUB: Multiply-subtract.

MSUBPT: Multiply-subtract checked pointer.

MUL: Multiply: an alias of MADD.

MVN: Bitwise NOT: an alias of ORN (shifted register).

NEG (shifted register): Negate (shifted register): an alias of SUB (shifted register).

NEGS: Negate, setting flags: an alias of SUBS (shifted register).

NGC: Negate with carry: an alias of SBC.

NGCS: Negate with carry, setting flags: an alias of SBCS.

NOP: No operation.

ORN (shifted register): Bitwise OR NOT (shifted register).

ORR (immediate): Bitwise OR (immediate).

ORR (shifted register): Bitwise OR (shifted register).

PACDA, PACDZA: Pointer Authentication Code for data address, using key A.

PACDB, PACDZB: Pointer Authentication Code for data address, using key B.

PACGA: Pointer Authentication Code, using generic key.

PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA: Pointer Authentication Code for instruction address, using key A.

PACIA171615: Pointer Authentication Code for instruction address, using key A.

PACIASPPC: Pointer Authentication Code for return address, using key A.

PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB: Pointer Authentication Code for instruction address, using key B.

PACIB171615: Pointer Authentication Code for instruction address, using key B.

PACIBSPPC: Pointer Authentication Code for return address, using key B.

PACM: Pointer authentication modifier.

PACNBIASPPC: Pointer Authentication Code for return address, using key A, not a branch target.

PACNBIBSPPC: Pointer Authentication Code for return address, using key B, not a branch target.

PRFM (immediate): Prefetch memory (immediate).

PRFM (literal): Prefetch memory (literal).

PRFM (register): Prefetch memory (register).

PRFUM: Prefetch memory (unscaled offset).

PSB: Profiling synchronization barrier.

PSSBB: Physical speculative store bypass barrier: an alias of DSB.

RBIT: Reverse bits.

RCWCAS, RCWCASA, RCWCASAL, RCWCASL: Read check write compare and swap doubleword in memory.

RCWCASP, RCWCASPA, RCWCASPAL, RCWCASPL: Read check write compare and swap quadword in memory.

RCWCLR, RCWCLRA, RCWCLRAL, RCWCLRL: Read check write atomic bit clear on doubleword in memory.

RCWCLRP, RCWCLRPA, RCWCLRPAL, RCWCLRPL: Read check write atomic bit clear on quadword in memory.

RCWSCAS, RCWSCASA, RCWSCASAL, RCWSCASL: Read check write software compare and swap doubleword in memory.

RCWSCASP, RCWSCASPA, RCWSCASPAL, RCWSCASPL: Read check write software compare and swap quadword in memory.

RCWSCLR, RCWSCLRA, RCWSCLRAL, RCWSCLRL: Read check write software atomic bit clear on doubleword in memory.

RCWSCLRP, RCWSCLRPA, RCWSCLRPAL, RCWSCLRPL: Read check write software atomic bit clear on quadword in memory.

RCWSET, RCWSETA, RCWSETAL, RCWSETL: Read check write atomic bit set on doubleword in memory.

RCWSETP, RCWSETPA, RCWSETPAL, RCWSETPL: Read check write atomic bit set on quadword in memory.

RCWSSET, RCWSSETA, RCWSSETAL, RCWSSETL: Read check write software atomic bit set on doubleword in memory.

RCWSSETP, RCWSSETPA, RCWSSETPAL, RCWSSETPL: Read check write software atomic bit set on quadword in memory.

RCWSSWP, RCWSSWPA, RCWSSWPAL, RCWSSWPL: Read check write software swap doubleword in memory.

RCWSSWPP, RCWSSWPPA, RCWSSWPPAL, RCWSSWPPL: Read check write software swap quadword in memory.

RCWSWP, RCWSWPA, RCWSWPAL, RCWSWPL: Read check write swap doubleword in memory.

RCWSWPP, RCWSWPPA, RCWSWPPAL, RCWSWPPL: Read check write swap quadword in memory.

RET: Return from subroutine.

RETAA, RETAB: Return from subroutine, with pointer authentication.

RETAASPPC, RETABSPPC: Return from subroutine, with enhanced pointer authentication using an immediate offset.

RETAASPPCR, RETABSPPCR: Return from subroutine, with enhanced pointer authentication using a register.

REV: Reverse bytes.

REV16: Reverse bytes in 16-bit halfwords.

REV32: Reverse bytes in 32-bit words.

REV64: Reverse bytes: an alias of REV.

RMIF: Rotate, mask insert flags.

ROR (immediate): Rotate right (immediate): an alias of EXTR.

ROR (register): Rotate right (register): an alias of RORV.

RORV: Rotate right variable.

RPRFM: Range prefetch memory.

SB: Speculation barrier.

SBC: Subtract with carry.

SBCS: Subtract with carry, setting flags.

SBFIZ: Signed bitfield insert in zeros: an alias of SBFM.

SBFM: Signed bitfield move.

SBFX: Signed bitfield extract: an alias of SBFM.

SDIV (quotient): Signed divide.

SETF8, SETF16: Evaluation of 8-bit or 16-bit flag values.

SETGP, SETGM, SETGE: Memory set with tag setting.

SETGPN, SETGMN, SETGEN: Memory set with tag setting, non-temporal.

SETGPT, SETGMT, SETGET: Memory set with tag setting, unprivileged.

SETGPTN, SETGMTN, SETGETN: Memory set with tag setting, unprivileged and non-temporal.

SETP, SETM, SETE: Memory set.

SETPN, SETMN, SETEN: Memory set, non-temporal.

SETPT, SETMT, SETET: Memory set, unprivileged.

SETPTN, SETMTN, SETETN: Memory set, unprivileged and non-temporal.

SEV: Send event.

SEVL: Send event local.

SHUH: Shared update hint.

SLBND: Scoped release boundary.

SMADDL: Signed multiply-add long.

SMAX (immediate): Signed maximum (immediate).

SMAX (register): Signed maximum (register).

SMC: Secure monitor call.

SMIN (immediate): Signed minimum (immediate).

SMIN (register): Signed minimum (register).

SMNEGL: Signed multiply-negate long: an alias of SMSUBL.

SMSTART: Enable access to Streaming SVE mode and SME architectural state: an alias of MSR (immediate).

SMSTOP: Disable access to Streaming SVE mode and SME architectural state: an alias of MSR (immediate).

SMSUBL: Signed multiply-subtract long.

SMULH: Signed multiply high.

SMULL (32-bit): Signed multiply long: an alias of SMADDL.

SRLS: Scope release.

SSBB: Speculative store bypass barrier: an alias of DSB.

ST2G: Store Allocation Tags.

ST64B: Single-copy atomic 64-byte store without status result.

ST64BV: Single-copy atomic 64-byte store with status result.

ST64BV0: Single-copy atomic 64-byte EL0 store with status result.

STADD, STADDL: Atomic add on word or doubleword, without return: an alias of LDADD, LDADDA, LDADDAL, LDADDL.

STADDB, STADDLB: Atomic add on byte, without return: an alias of LDADDB, LDADDAB, LDADDALB, LDADDLB.

STADDH, STADDLH: Atomic add on halfword, without return: an alias of LDADDH, LDADDAH, LDADDALH, LDADDLH.

STCLR, STCLRL: Atomic bit clear on word or doubleword, without return: an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL.

STCLRB, STCLRLB: Atomic bit clear on byte, without return: an alias of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB.

STCLRH, STCLRLH: Atomic bit clear on halfword, without return: an alias of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.

STCPH: Store concurrent priority hint.

STEOR, STEORL: Atomic exclusive-OR on word or doubleword, without return: an alias of LDEOR, LDEORA, LDEORAL, LDEORL.

STEORB, STEORLB: Atomic exclusive-OR on byte, without return: an alias of LDEORB, LDEORAB, LDEORALB, LDEORLB.

STEORH, STEORLH: Atomic exclusive-OR on halfword, without return: an alias of LDEORH, LDEORAH, LDEORALH, LDEORLH.

STG: Store Allocation Tag.

STGM: Store Allocation Tag multiple.

STGP: Store Allocation Tag and pair of registers.

STILP: Store-release ordered pair of registers.

STL64B: Single-copy atomic 64-byte store-release without status result.

STL64BV: Single-copy atomic 64-byte store-release with status result.

STL64BV0: Single-copy atomic 64-byte EL0 store-release with status result.

STLLR: Store LORelease register.

STLLRB: Store LORelease register byte.

STLLRH: Store LORelease register halfword.

STLP: Store-release pair of registers.

STLR: Store-release register.

STLRB: Store-release register byte.

STLRH: Store-release register halfword.

STLTXR: Store-release unprivileged exclusive register.

STLUR: Store-release register (unscaled).

STLURB: Store-release register byte (unscaled).

STLURH: Store-release register halfword (unscaled).

STLXP: Store-release exclusive pair of registers.

STLXR: Store-release exclusive register.

STLXRB: Store-release exclusive register byte.

STLXRH: Store-release exclusive register halfword.

STNP: Store pair of registers, with non-temporal hint.

STP: Store pair of registers.

STR (immediate): Store register (immediate).

STR (register): Store register (register).

STRB (immediate): Store register byte (immediate).

STRB (register): Store register byte (register).

STRH (immediate): Store register halfword (immediate).

STRH (register): Store register halfword (register).

STSET, STSETL: Atomic bit set on word or doubleword, without return: an alias of LDSET, LDSETA, LDSETAL, LDSETL.

STSETB, STSETLB: Atomic bit set on byte, without return: an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB.

STSETH, STSETLH: Atomic bit set on halfword, without return: an alias of LDSETH, LDSETAH, LDSETALH, LDSETLH.

STSHH: Store shared hint.

STSMAX, STSMAXL: Atomic signed maximum on word or doubleword, without return: an alias of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.

STSMAXB, STSMAXLB: Atomic signed maximum on byte, without return: an alias of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.

STSMAXH, STSMAXLH: Atomic signed maximum on halfword, without return: an alias of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.

STSMIN, STSMINL: Atomic signed minimum on word or doubleword, without return: an alias of LDSMIN, LDSMINA, LDSMINAL, LDSMINL.

STSMINB, STSMINLB: Atomic signed minimum on byte, without return: an alias of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.

STSMINH, STSMINLH: Atomic signed minimum on halfword, without return: an alias of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH.

STTADD, STTADDL: Atomic add unprivileged, without return: an alias of LDTADD, LDTADDA, LDTADDAL, LDTADDL.

STTCLR, STTCLRL: Atomic bit clear unprivileged, without return: an alias of LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL.

STTNP: Store unprivileged pair of registers, with non-temporal hint.

STTP: Store unprivileged pair of registers.

STTR: Store register (unprivileged).

STTRB: Store register byte (unprivileged).

STTRH: Store register halfword (unprivileged).

STTSET, STTSETL: Atomic bit set unprivileged, without return: an alias of LDTSET, LDTSETA, LDTSETAL, LDTSETL.

STTXR: Store unprivileged exclusive register.

STUMAX, STUMAXL: Atomic unsigned maximum on word or doubleword, without return: an alias of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.

STUMAXB, STUMAXLB: Atomic unsigned maximum on byte, without return: an alias of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.

STUMAXH, STUMAXLH: Atomic unsigned maximum on halfword, without return: an alias of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.

STUMIN, STUMINL: Atomic unsigned minimum on word or doubleword, without return: an alias of LDUMIN, LDUMINA, LDUMINAL, LDUMINL.

STUMINB, STUMINLB: Atomic unsigned minimum on byte, without return: an alias of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.

STUMINH, STUMINLH: Atomic unsigned minimum on halfword, without return: an alias of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.

STUR: Store register (unscaled).

STURB: Store register byte (unscaled).

STURH: Store register halfword (unscaled).

STXP: Store exclusive pair of registers.

STXR: Store exclusive register.

STXRB: Store exclusive register byte.

STXRH: Store exclusive register halfword.

STZ2G: Store Allocation Tags, zeroing.

STZG: Store Allocation Tag, zeroing.

STZGM: Store Allocation Tag and zero multiple.

SUB (extended register): Subtract extended and scaled register.

SUB (immediate): Subtract immediate value.

SUB (shifted register): Subtract optionally-shifted register.

SUBG: Subtract with tag.

SUBP: Subtract pointer.

SUBPS: Subtract pointer, setting flags.

SUBPT: Subtract checked pointer.

SUBS (extended register): Subtract extended and scaled register, setting flags.

SUBS (immediate): Subtract immediate value, setting flags.

SUBS (shifted register): Subtract optionally-shifted register, setting flags.

SVC: Supervisor call.

SWP, SWPA, SWPAL, SWPL: Swap word or doubleword in memory.

SWPB, SWPAB, SWPALB, SWPLB: Swap byte in memory.

SWPH, SWPAH, SWPALH, SWPLH: Swap halfword in memory.

SWPP, SWPPA, SWPPAL, SWPPL: Swap quadword in memory.

SWPT, SWPTA, SWPTAL, SWPTL: Swap unprivileged.

SXTB: Signed extend byte: an alias of SBFM.

SXTH: Sign extend halfword: an alias of SBFM.

SXTW: Sign extend word: an alias of SBFM.

SYS: System instruction.

SYSL: System instruction with result.

SYSP: 128-bit system instruction.

TBNZ: Test bit and branch if nonzero.

TBZ: Test bit and branch if zero.

TFLTNZ: Test bit and fault if nonzero.

TFLTZ: Test bit and fault if zero.

TLBI: TLB invalidate operation: an alias of SYS.

TLBIP: TLB invalidate pair operation: an alias of SYSP.

TRCIT: Trace instrumentation: an alias of SYS.

TSB: Trace synchronization barrier.

TST (immediate): Test bits (immediate): an alias of ANDS (immediate).

TST (shifted register): Test (shifted register): an alias of ANDS (shifted register).

UBFIZ: Unsigned bitfield insert in zeros: an alias of UBFM.

UBFM: Unsigned bitfield move.

UBFX: Unsigned bitfield extract: an alias of UBFM.

UDF: Permanently undefined.

UDIV (quotient): Unsigned divide.

UMADDL: Unsigned multiply-add long.

UMAX (immediate): Unsigned maximum (immediate).

UMAX (register): Unsigned maximum (register).

UMIN (immediate): Unsigned minimum (immediate).

UMIN (register): Unsigned minimum (register).

UMNEGL: Unsigned multiply-negate long: an alias of UMSUBL.

UMSUBL: Unsigned multiply-subtract long.

UMULH: Unsigned multiply high.

UMULL (32-bit): Unsigned multiply long: an alias of UMADDL.

UXTB: Unsigned extend byte: an alias of UBFM.

UXTH: Unsigned extend halfword: an alias of UBFM.

WFE: Wait for event.

WFET: Wait for event with timeout.

WFI: Wait for interrupt.

WFIT: Wait for interrupt with timeout.

XAFLAG: Convert floating-point condition flags from external format to Arm format.

XPACD, XPACI, XPACLRI: Strip Pointer Authentication Code.

YIELD: Yield.

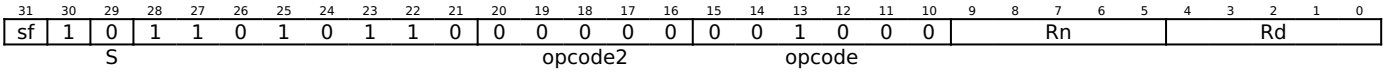
ABS

Absolute value

This instruction calculates the absolute value of the signed integer value in the source register, and writes the result to the destination register. If the value in the source register is the most negative value, the result is the same as the value in the source register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ABS <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ABS <Xd>, <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let datasize : integer{} = 32 << UInt(sf);
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = Abs(SInt(operand1));

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

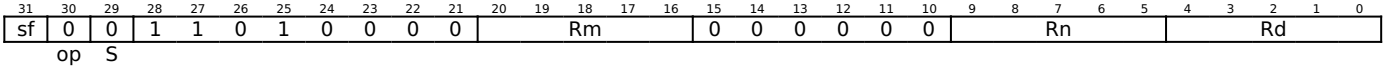
ADC

Add with carry

This instruction adds two register values and the Carry flag value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ADC <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ADC <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, PSTATE.C);

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

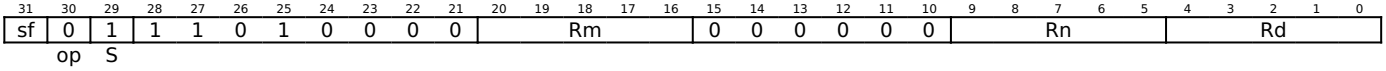
ADCS

Add with carry, setting flags

This instruction adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ADCS <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ADCS <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, PSTATE.C);

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

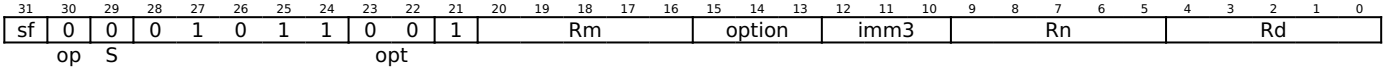
ADD (extended register)

Add extended and scaled register

This instruction adds a register value and a sign-extended or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer{} = UInt(imm3) as integer{0..4};
let datasize : integer{} = 32 << UInt(sf);
let extend_type : ExtendType = DecodeRegExtend(option);
```

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = ExtendReg{datasize}(m, extend_type, shift);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '0');

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

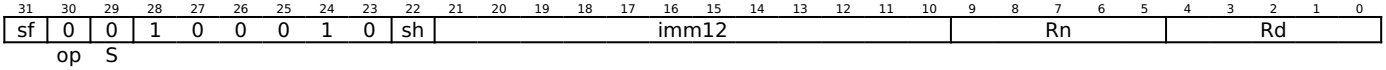
2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

ADD (immediate)

Add immediate value

This instruction adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.
This instruction is used by the alias MOV (to/from SP).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ADD <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);

let imm : bits(24) = if sh == '0' then Zeros{12}::imm12 else imm12::Zeros{12};
```

Assembler Symbols

<Wd|WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn|WSP>	Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm>	Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift>	Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
MOV (to/from SP)	`sh == '0' && imm12 == '000000000000' && (Rd == '11111' || Rn == '11111')`

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = ZeroExtend{}(imm);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '0');

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

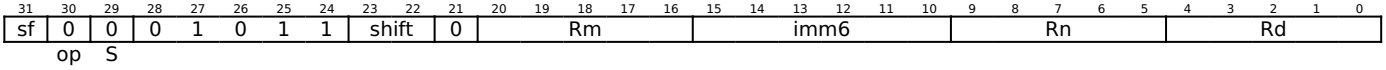
2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

ADD (shifted register)

Add optionally-shifted register

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ADD <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ADD <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '0');

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

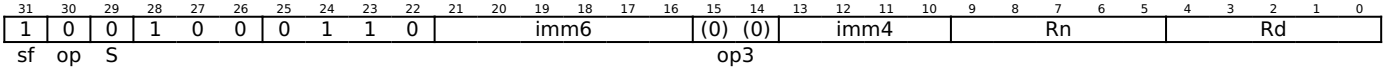
ADDG

Add with tag

This instruction adds an immediate value scaled by the Tag Granule to the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

Integer

(FEAT_MTE)



Encoding

```
ADDG <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let tag_offset : bits(4) = imm4;
let offset : bits(64) = LSL(ZeroExtend{64}(imm6), LOG2_TAG_GRANULE);
```

Assembler Symbols

<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<uimm6>	Is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the "imm6" field.
<uimm4>	Is an unsigned immediate, in the range 0 to 15, encoded in the "imm4" field.

Operation

```
let operand1 : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let start_tag : bits(4) = AArch64_AllocationTagFromAddress(operand1);
let exclude : bits(16) = GCR_EL1().Exclude;
let rtag : bits(4) = AArch64_ChooseNonExcludedTagOrZero(start_tag, tag_offset, exclude);
var result : bits(64);

(result, -) = AddWithCarry{64}(operand1, offset, '0');

result = AArch64_AddressWithAllocationTag(result, rtag);

if d == 31 then
    SP{64}() = result;
else
    X{64}(d) = result;
end;
```

ADDPT

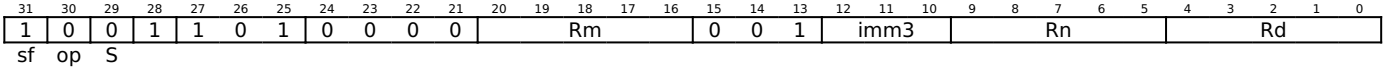
Add checked pointer

This instruction adds a base address register value and an optionally-shifted register value, and writes the result to the destination register. The optionally-shifted register value is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)



Encoding

```
ADDPT <Xd|SP>, <Xn|SP>, <Xm>{, LSL #<amount>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CPA) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer = UInt(imm3);
```

Assembler Symbols

<Xd|SP>	Is the 64-bit name of the general-purpose destination register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the first general-purpose source register or stack pointer, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<amount>	Is the left shift amount, in the range 0 to 7, defaulting to 0, encoded in the "imm3" field.

Operation

```
var result : bits(64);
let base : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let offset : bits(64) = LSL(X{64}(m), shift);

result = base + offset;
result = PointerAddCheck(result, base);

if d == 31 then
    SP{64}() = result;
else
    X{64}(d) = result;
end;
```

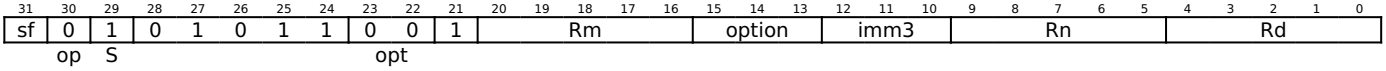
ADDS (extended register)

Add extended and scaled register, setting flags

This instruction adds a register value and a sign-extended or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMN (extended register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ADDS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ADDS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer{} = UInt(imm3) as integer{0..4};
let datasize : integer{} = 32 << UInt(sf);
let extend_type : ExtendType = DecodeRegExtend(option);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CMN (extended register)	`Rd == '11111'`

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = ExtendReg{datasize}(m, extend_type, shift);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '0');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

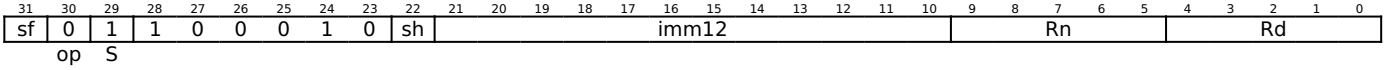
ADDS (immediate)

Add immediate value, setting flags

This instruction adds a register value and an optionally-shifted immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMN (immediate).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ADDS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ADDS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);

let imm : bits(24) = if sh == '0' then Zeros{12}::imm12 else imm12::Zeros{12};
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn|WSP>	Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm>	Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift>	Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
CMN (immediate)	`Rd == '11111'`

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = ZeroExtend{}(imm);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '0');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

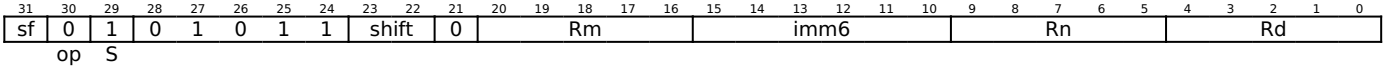
ADDS (shifted register)

Add optionally-shifted register, setting flags

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMN (shifted register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ADDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ADDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CMN (shifted register)	`Rd == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '0');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

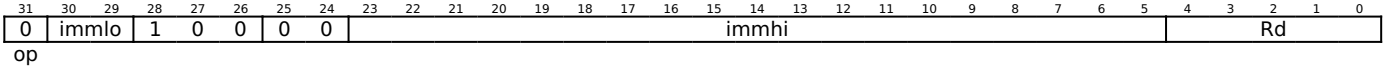
ADR

Form PC-relative address

This instruction adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.



Encoding

```
ADR <Xd>, <label>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let imm : bits(64) = SignExtend{}(immhi::immlo);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<label>	Is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in "immhi:immlo".

Operation

```
X{64}(d) = PC64() + imm;
```

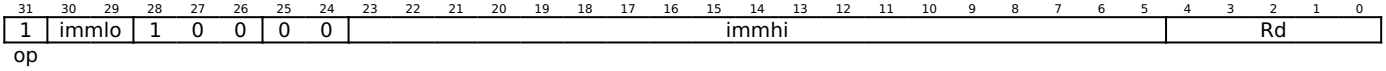
2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

ADRP

Form PC-relative address to 4KB page

This instruction adds an immediate value that is shifted left by 12 bits, to the PC value to form a PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.



Encoding

```
ADRP <Xd>, <label>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let imm : bits(64) = SignExtend{}(immhi::immlo::Zeros{12});
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<label>	Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

Operation

```
let base : bits(64) = PC64()[63:12]::Zeros{12};
X{64}(d) = base + imm;
```

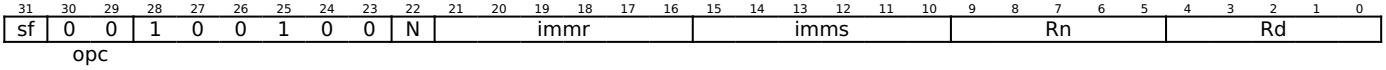
AND (immediate)

Bitwise AND (immediate)

This instruction performs a bitwise AND between a register value and an immediate value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
AND <Wd|WSP>, <Wn>, #<imm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
AND <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
var imm : bits(datasize);
(imm, -) = DecodeBitMasks{datasize}(N, imms, immr, TRUE);
```

Assembler Symbols

<Wd|WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	Is the bitmask immediate. For encoding information, see *Logical (immediate)*.
<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = imm;
let result : bits(datasize) = operand1 AND operand2;

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

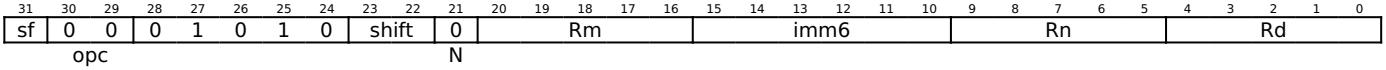
AND (shifted register)

Bitwise AND (shifted register)

This instruction performs a bitwise AND between a register value and an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
AND <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
AND <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 AND operand2;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

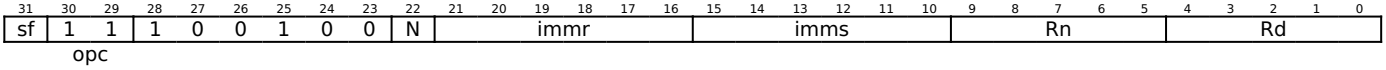
ANDS (immediate)

Bitwise AND (immediate), setting flags

This instruction performs a bitwise AND between a register value and an immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (immediate).



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
ANDS <Wd>, <Wn>, #<imm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ANDS <Xd>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
var imm : bits(datasize);
(imm, -) = DecodeBitMasks{datasize}(N, imms, immr, TRUE);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	Is the bitmask immediate. For encoding information, see *Logical (immediate)*.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
TST (immediate)	`Rd == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = imm;
let result : bits(datasize) = operand1 AND operand2;

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = result[datasize-1]::IsZeroBit{datasize}(result)::'00';
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

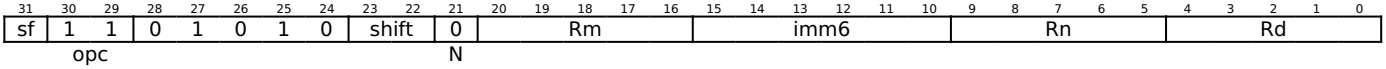
ANDS (shifted register)

Bitwise AND (shifted register), setting flags

This instruction performs a bitwise AND between a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (shifted register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ANDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ANDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
TST (shifted register)	`Rd == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 AND operand2;

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = result[datasize-1]::IsZeroBit{datasize}(result)::'00';
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

2026-09_rel 2026-09-21 14:22:38

APAS

Associate physical address space

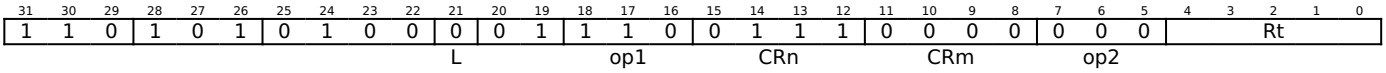
This instruction associates a physical address space with a memory-mapped location that is protected by a memory-side physical address space filter.
For more information, see APAS, Associate PA space.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_RME_GPC3)



Encoding

```
APAS <Xt>
```

is equivalent to

```
SYS #6, C7, C0, #0, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

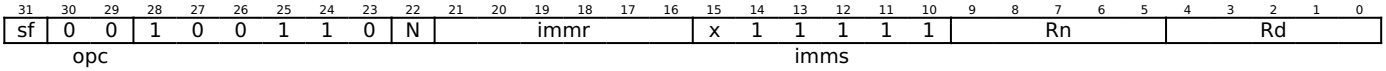
ASR (immediate)

Arithmetic shift right (immediate)

This instruction shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms == 011111)`

```
ASR <Wd>, <Wn>, #<shift>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #<shift>, #31
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1 && imms == 111111)`

```
ASR <Xd>, <Xn>, #<shift>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #<shift>, #63
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

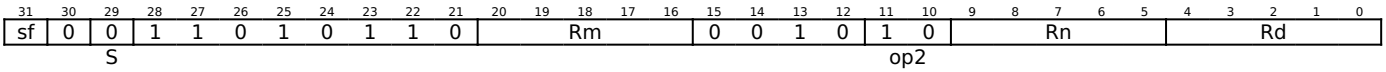
ASR (register)

Arithmetic shift right (register)

This instruction shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of ASRV. This means:

- The encodings in this description are named to match the encodings of ASRV.
- The description of ASRV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ASR <Wd>, <Wn>, <Wm>
```

is equivalent to

```
ASRV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ASR <Xd>, <Xn>, <Xm>
```

is equivalent to

```
ASRV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of ASRV gives the operational pseudocode for this instruction.

Operational Information

The description of ASRV gives the operational information for this instruction.

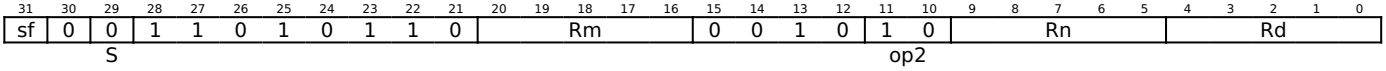
ASRV

Arithmetic shift right variable

This instruction shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ASR (register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ASRV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ASRV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(op2);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
let operand2 : bits(datasize) = X{datasize}(m);

X{datasize}(d) = ShiftReg{datasize}(n, shift_type, UInt(operand2) MOD datasize);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

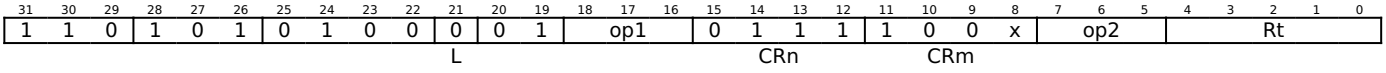
AT

Address translate

For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions*.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

`AT <at_op>, <Xt>`

is equivalent to

`SYS #<op1>, C7, <Cm>, #<op2>, <Xt>`

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_AT`.

Assembler Symbols

<at_op> Is an AT operation name, as listed for the AT system instruction group, encoded in “(op1 :: CRm :: op2)”:

op1	CRm	op2	<at_op>	Architectural Feature	Description
000	1000	000	S1E1R	–	For more information, see AT S1E1R.
000	1000	001	S1E1W	–	For more information, see AT S1E1W.
000	1000	010	S1E0R	–	For more information, see AT S1E0R.
000	1000	011	S1E0W	–	For more information, see AT S1E0W.
000	1001	000	S1E1RP	FEAT_PAN2	For more information, see AT S1E1RP.
000	1001	001	S1E1WP	FEAT_PAN2	For more information, see AT S1E1WP.

AUTDA, AUTDZA

Authenticate data address, using key A

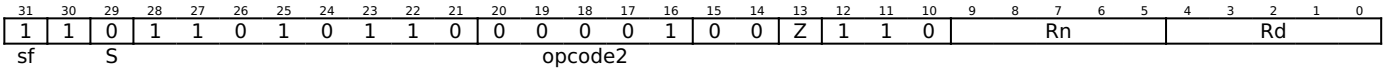
This instruction authenticates a data address, using a modifier and key A.
The address is in the general-purpose register that is specified by <Xd>.
The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP>, for `AUTDA`.
- The value zero, for `AUTDZA`.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

Integer

(FEAT_PAuth)



Encoding for the AUTDA variant

Applies when `(Z == 0)`

```
AUTDA <Xd>, <Xn|SP>
```

Encoding for the AUTDZA variant

Applies when `(Z == 1 && Rn == 11111)`

```
AUTDZA <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;
let auth_combined : boolean = FALSE;

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);

let source_is_sp : boolean = Z == '0' && n == 31;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X{64}(d) = AuthDA(X{64}(d), SP{64}(), auth_combined);
else
    X{64}(d) = AuthDA(X{64}(d), X{64}(n), auth_combined);
end;
```

AUTDB, AUTDZB

Authenticate data address, using key B

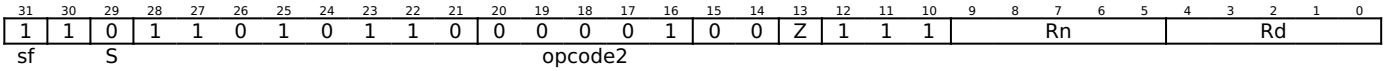
This instruction authenticates a data address, using a modifier and key B.
The address is in the general-purpose register that is specified by <Xd>.
The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDB.
- The value zero, for AUTDZB.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

Integer

(FEAT_PAuth)



Encoding for the AUTDB variant

Applies when `(Z == 0)`

```
AUTDB <Xd>, <Xn|SP>
```

Encoding for the AUTDZB variant

Applies when `(Z == 1 && Rn == 11111)`

```
AUTDZB <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;
let auth_combined : boolean = FALSE;

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);

let source_is_sp : boolean = Z == '0' && n == 31;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X{64}(d) = AuthDB(X{64}(d), SP{64}(), auth_combined);
else
    X{64}(d) = AuthDB(X{64}(d), X{64}(n), auth_combined);
end;
```

AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA

Authenticate instruction address, using key A

This instruction authenticates an instruction address, using a modifier and key A.
If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.
The address is:

- In the general-purpose register that is specified by <Xd> for AUTIA and AUTIZA.
- In X17, for AUTIA1716.
- In X30, for AUTIASP and AUTIAZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIA.
- The value zero, for AUTIZA and AUTIAZ.
- In X16, for AUTIA1716.
- In SP, for AUTIASP.

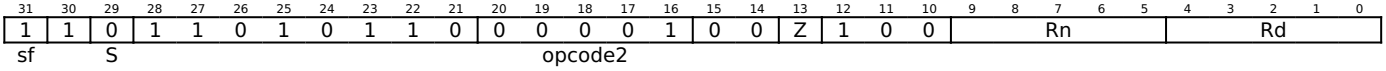
If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then AUTIA1716 and AUTIASP include a second modifier that is:

- In X15, for AUTIA1716.
- In X16, for AUTIASP.

It has encodings from 2 classes: Integer and System

Integer

(FEAT_PAuth)



Encoding for the AUTIA variant

Applies when (Z == 0)

```
AUTIA <Xd>, <Xn|SP>
```

Encoding for the AUTIZA variant

Applies when (Z == 1 && Rn == 11111)

```
AUTIZA <Xd>
```

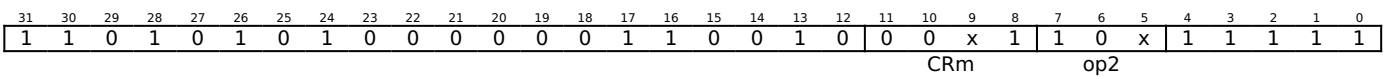
Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let source_is_sp : boolean = Z == '0' && n == 31;
let autia1716 : boolean = FALSE;
let auth_combined : boolean = FALSE;
```

System

(FEAT_PAuth)



Encoding for the AUTIA1716 variant

Applies when (CRm == 0001 && op2 == 100)

```
AUTIA1716
```

Encoding for the AUTIASP variant

Applies when (CRm == 0011 && op2 == 101)

```
AUTIASP
```

Encoding for the AUTIAZ variant

Applies when (CRm == 0011 && op2 == 100)

AUTIAZ

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_NOP); end;

var d : integer;
var n : integer;
var source_is_sp : boolean = FALSE;
var autia1716 : boolean = FALSE;
let auth_combined : boolean = FALSE;

case CRm::op2 of
    when '0011 100' => // AUTIAZ
        d = 30;
        n = 31;
    when '0011 101' => // AUTIASP
        d = 30;
        source_is_sp = TRUE;
    when '0001 100' => // AUTIA1716
        d = 17;
        n = 16;
        autia1716 = TRUE;
end;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    if IsFeatureImplemented(FEAT_PAuth_LR) && PSTATE.PACM == '1' then
        X{64}(d) = AuthIA2(X{64}(d), SP{64}(), X{64}(16), auth_combined);
    else
        X{64}(d) = AuthIA(X{64}(d), SP{64}(), auth_combined);
    end;
else
    if IsFeatureImplemented(FEAT_PAuth_LR) && PSTATE.PACM == '1' && autia1716 then
        X{64}(d) = AuthIA2(X{64}(d), X{64}(n), X{64}(15), auth_combined);
    else
        X{64}(d) = AuthIA(X{64}(d), X{64}(n), auth_combined);
    end;
end;
```

AUTIA171615

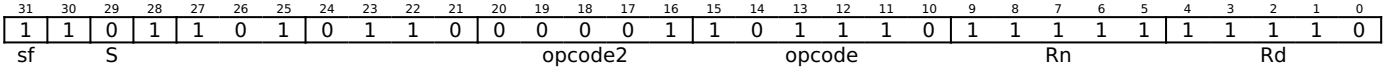
Authenticate instruction address, using key A

This instruction authenticates an instruction address, using two modifiers and key A. The address is in X17. The 64-bit value of modifier1 is the value in X16. The 64-bit value of modifier2 is the value in X15.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

Integer

(FEAT_PAuth_LR)



Encoding

AUTIA171615

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth_LR) then EndOfDecode(Decode_UNDEF); end;
```

Operation

```
let is_combined : boolean = FALSE;
X{64}(17) = AuthIA2(X{64}(17), X{64}(16), X{64}(15), is_combined);
```

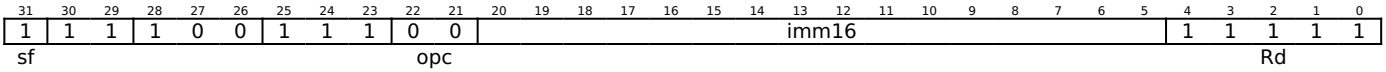
AUTIASPPC

Authenticate return address using key A, using an immediate offset

This instruction authenticates an instruction address, using two modifiers and key A.
If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.
The address is in X30.
The first modifier is in SP.
The second modifier is the address of a program label.

Integer

(FEAT_PAuth_LR)



Encoding

```
AUTIASPPC <label>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth_LR) then EndOfDecode(Decode_UNDEF); end;

let d : integer = 30;
let offset : bits(64) = ZeroExtend{}(imm16::'00');
let auth_combined : boolean = FALSE;
```

Assembler Symbols

<label>	Is the program label whose address is to be calculated. Its negative offset from the address of this instruction, a multiple of 4 in the range -262140 to 0, is encoded as an unsigned value in the "imm16" field as <label>/4.

Operation

```
let pac_addr : bits(64) = PC64() - offset;

X{64}(d) = AuthIA2(X{64}(d), SP{64}(), pac_addr, auth_combined);
```

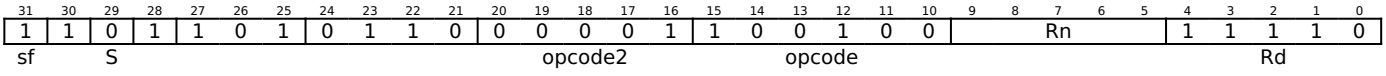
AUTIASPPCR

Authenticate return address using key A, using a register

This instruction authenticates an instruction address, using two modifiers and key A.
If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.
The address is in X30.
The first modifier is in SP.
The second modifier is in the general-purpose register that is specified by <Xn>.

Integer

(FEAT_PAuth_LR)



Encoding

```
AUTIASPPCR <Xn>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth_LR) then EndOfDecode(Decode_UNDEF); end;

let d : integer = 30;
let n : integer = UInt(Rn);
let auth_combined : boolean = FALSE;
```

Assembler Symbols

<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
X{64}(d) = AuthIA2(X{64}(d), SP{64}(), X{64}(n), auth_combined);
```

AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB

Authenticate instruction address, using key B

This instruction authenticates an instruction address, using a modifier and key B.
If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.
The address is:

- In the general-purpose register that is specified by <Xd> for `AUTIB` and `AUTIZB`.
- In X17, for `AUTIB1716`.
- In X30, for `AUTIBSP` and `AUTIBZ`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for `AUTIB`.
- The value zero, for `AUTIZB` and `AUTIBZ`.
- In X16, for `AUTIB1716`.
- In SP, for `AUTIBSP`.

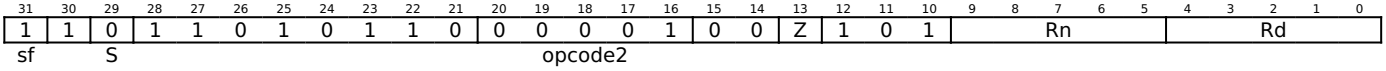
If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then `AUTIB1716` and `AUTIBSP` include a second modifier that is:

- In X15, for `AUTIB1716`.
- In X16, for `AUTIBSP`.

It has encodings from 2 classes: Integer and System

Integer

(FEAT_PAuth)



Encoding for the AUTIB variant

Applies when `(Z == 0)`

```
AUTIB <Xd>, <Xn|SP>
```

Encoding for the AUTIZB variant

Applies when `(Z == 1 && Rn == 11111)`

```
AUTIZB <Xd>
```

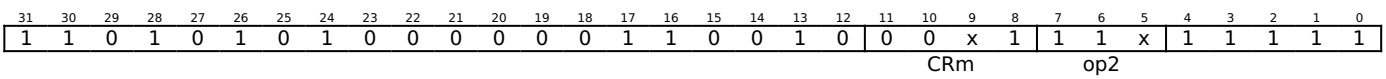
Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let source_is_sp : boolean = Z == '0' && n == 31;
let autib1716 : boolean = FALSE;
let auth_combined : boolean = FALSE;
```

System

(FEAT_PAuth)



Encoding for the AUTIB1716 variant

Applies when `(CRm == 0001 && op2 == 110)`

```
AUTIB1716
```

Encoding for the AUTIBSP variant

Applies when `(CRm == 0011 && op2 == 111)`

```
AUTIBSP
```

Encoding for the AUTIBZ variant

Applies when `(CRm == 0011 && op2 == 110)`

AUTIBZ

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_NOP); end;

var d : integer;
var n : integer;
var source_is_sp : boolean = FALSE;
var autib1716 : boolean = FALSE;
let auth_combined : boolean = FALSE;

case CRm::op2 of
    when '0011 110' => // AUTIBZ
        d = 30;
        n = 31;
    when '0011 111' => // AUTIBSP
        d = 30;
        source_is_sp = TRUE;
    when '0001 110' => // AUTIB1716
        d = 17;
        n = 16;
        autib1716 = TRUE;
end;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    if IsFeatureImplemented(FEAT_PAuth_LR) && PSTATE.PACM == '1' then
        X{64}(d) = AuthIB2(X{64}(d), SP{64}(), X{64}(16), auth_combined);
    else
        X{64}(d) = AuthIB(X{64}(d), SP{64}(), auth_combined);
    end;
else
    if IsFeatureImplemented(FEAT_PAuth_LR) && PSTATE.PACM == '1' && autib1716 then
        X{64}(d) = AuthIB2(X{64}(d), X{64}(n), X{64}(15), auth_combined);
    else
        X{64}(d) = AuthIB(X{64}(d), X{64}(n), auth_combined);
    end;
end;
```

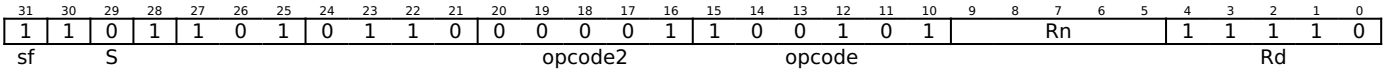
AUTIBSPPCR

Authenticate return address using key B, using a register

This instruction authenticates an instruction address, using two modifiers and key B.
If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.
The address is in X30.
The first modifier is in SP.
The second modifier is in the general-purpose register that is specified by <Xn>.

Integer

(FEAT_PAuth_LR)



Encoding

```
AUTIBSPPCR <Xn>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth_LR) then EndOfDecode(Decode_UNDEF); end;

let d : integer = 30;
let n : integer = UInt(Rn);
let auth_combined : boolean = FALSE;
```

Assembler Symbols

<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
X{64}(d) = AuthIB2(X{64}(d), SP{64}(), X{64}(n), auth_combined);
```

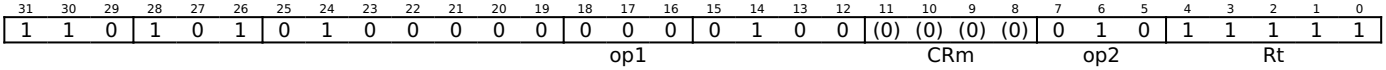
AXFLAG

Convert floating-point condition flags from Arm to external format

This instruction converts the state of the PSTATE.{N,Z,C,V} flags from a form representing the result of an Arm floating-point scalar compare instruction to an alternative representation required by some software.

System

(FEAT_FlagM2)



Encoding

AXFLAG

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_FlagM2) then EndOfDecode(Decode_UNDEF); end;
```

Operation

```
let z : bit = PSTATE.Z OR PSTATE.V;
let c : bit = PSTATE.C AND NOT PSTATE.V;

PSTATE.[N,Z,C,V] = '0' :: z :: c :: '0';
```

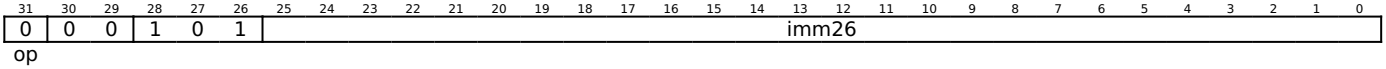
B

Branch

This instruction branches unconditionally to a label at a PC-relative offset. This instruction provides a hint that this is not a subroutine call or return.



Encoding

```
B <label>
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm26::'00');
```

Assembler Symbols

<label>	Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

Operation

```
let branch_conditional : boolean = FALSE;
BranchTo{64}(PC64() + offset, BranchType_DIR, branch_conditional);
```

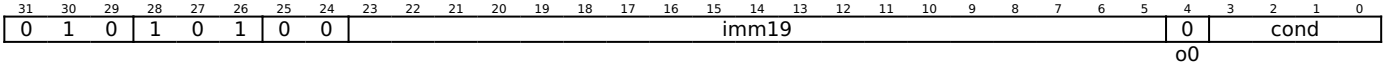
B.cond

Branch conditionally

This instruction branches conditionally to a label at a PC-relative offset. This instruction provides a hint that this is not a subroutine call or return.



Encoding

B.<cond> <label>

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm19::'00');
let condition : bits(4) = cond;
```

Assembler Symbols

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
let branch_conditional : boolean = TRUE;
if ConditionHolds(condition) then
    BranchTo{64}(PC64() + offset, BranchType_DIR, branch_conditional);
else
    BranchNotTaken(BranchType_DIR, branch_conditional);
end;
```

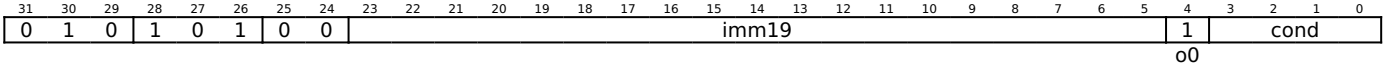
BC.cond

Branch consistent conditionally

This instruction branches conditionally to a label at a PC-relative offset, with a hint that this branch is very unlikely to change direction. This instruction provides a hint that this is not a subroutine call or return.

19-bit signed PC-relative branch offset

(FEAT_HBC)



Encoding

```
BC.<cond> <label>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_HBC) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm19::'00');
let condition : bits(4) = cond;
```

Assembler Symbols

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
let branch_conditional : boolean = TRUE;
if ConditionHolds(condition) then
    BranchTo{64}(PC64() + offset, BranchType_DIR, branch_conditional);
else
    BranchNotTaken(BranchType_DIR, branch_conditional);
end;
```

BFC

Bitfield clear

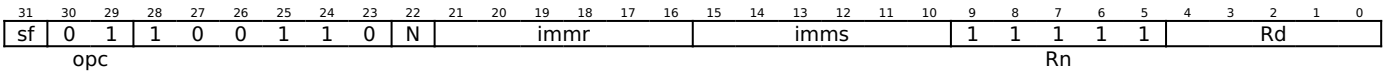
This instruction sets a bitfield of <width> bits at bit position <lsb> of the destination register to zero, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Leaving other bits unchanged

(FEAT_ASMv8p2)



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
BFC <Wd>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Wd>, WZR, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
BFC <Xd>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Xd>, XZR, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational Information

The description of BFM gives the operational information for this instruction.

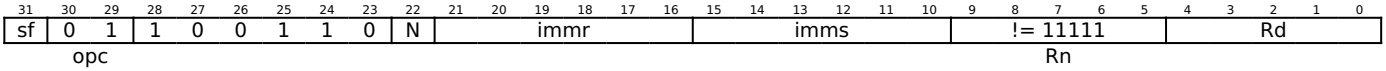
BFI

Bitfield insert

This instruction copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
BFI <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
BFI <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational Information

The description of BFM gives the operational information for this instruction.

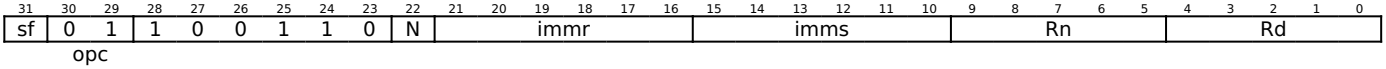
BFM

Bitfield move

This instruction is usually accessed using one of its aliases, which are always preferred for disassembly.
If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.
If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.
In both cases, the other bits of the destination register remain unchanged.
This instruction is used by the aliases BFC, BFI, and BFXIL.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
BFM <Wd>, <Wn>, #<immr>, #<imms>
```

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
BFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
if sf == '1' && N != '1' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && (N != '0' || immr[5] != '0' || imms[5] != '0') then
    EndOfDecode(Decode_UNDEF);
end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let r : integer = UInt(immr);

var wmask : bits(datasize);
var tmask : bits(datasize);
(wmask, tmask) = DecodeBitMasks{datasize}(N, imms, immr, FALSE);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<immr>	For the "32-bit" variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the "64-bit" variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
<imms>	For the "32-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the "64-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
BFC	`Rn == '11111' && UInt(imms) < UInt(immr)`
BFI	`Rn != '11111' && UInt(imms) < UInt(immr)`
BFXIL	`UInt(imms) >= UInt(immr)`

Operation

```
let src : bits(datasize) = X{}(n);

let dst : bits(datasize) = X{}(d);

// Perform bitfield move on low bits
let bot : bits(datasize) = (dst AND NOT wmask) OR (ROR(src, r) AND wmask);

// Combine extension bits and result bits
X{datasize}(d) = (dst AND NOT tmask) OR (bot AND tmask);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

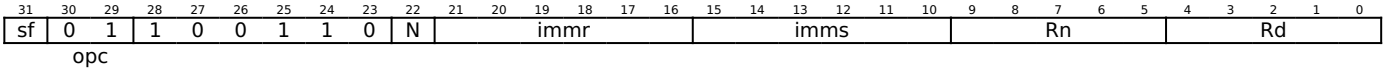
BFXIL

Bitfield extract and insert at low end

This instruction copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
BFXIL <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
BFXIL <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational Information

The description of BFM gives the operational information for this instruction.

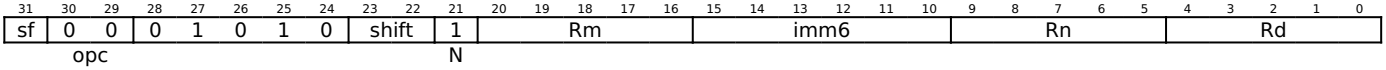
BIC (shifted register)

Bitwise bit clear (shifted register)

This instruction performs a bitwise AND between a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
BIC <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
BIC <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 AND NOT operand2;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

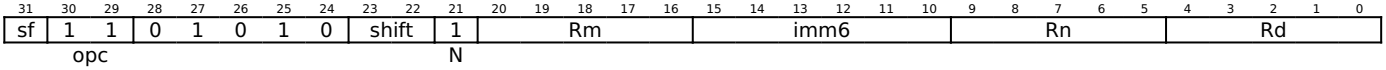
BICS (shifted register)

Bitwise bit clear (shifted register), setting flags

This instruction performs a bitwise AND between a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
BICS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
BICS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 AND NOT operand2;

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = result[datasize-1]::IsZeroBit{datasize}(result)::'00';
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

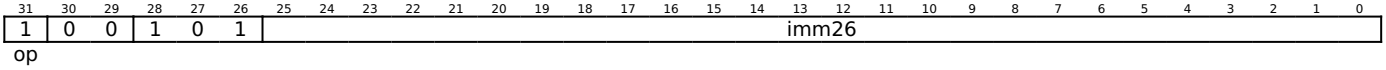
BL

Branch with link

This instruction branches to a PC-relative offset, setting register X30 to PC+4. This instruction provides a hint that this is a subroutine call.



Encoding

BL <label>

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm26::'00');
let d : integer = 30;
```

Assembler Symbols

<label>	Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

Operation

```
if IsFeatureImplemented(FEAT_GCS) && GCSPCREnabled(PSTATE.EL) then
    AddGCSRecord(PC64() + 4);
end;
X{64}(d) = PC64() + 4;

let branch_conditional : boolean = FALSE;
BranchTo{64}(PC64() + offset, BranchType_DIRCALL, branch_conditional);
```

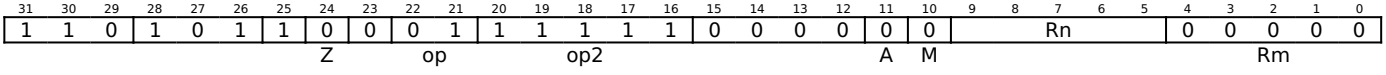
BLR

Branch with link to register

This instruction calls a subroutine at an address in a register, setting register X30 to PC+4. This instruction provides a hint that this is a subroutine call.



Encoding

```
BLR <Xn>
```

Decode for this encoding

```
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xn>	Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

```
let target : bits(64) = X{}(n);
if IsFeatureImplemented(FEAT_GCS) && GCSPCREnabled(PSTATE.EL) then
    AddGCSRecord(PC64() + 4);
end;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '10';

X{64}(30) = PC64() + 4;

let branch_conditional : boolean = FALSE;
BranchTo{64}(target, BranchType_INDCALL, branch_conditional);
```

BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with link to register, with pointer authentication

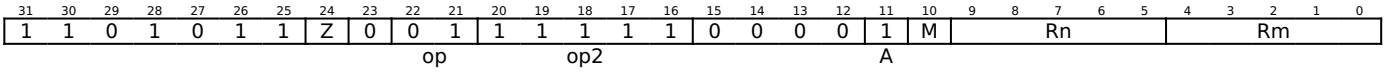
This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.
The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP>, for BLRAA and BLRAB.
- The value zero, for BLRAAZ and BLRABZ.

Key A is used for BLRAA and BLRAAZ. Key B is used for BLRAB and BLRABZ.
If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.
The authenticated address is not written back to the general-purpose register.
This instruction provides a hint that this is a subroutine call.

Integer

(FEAT_PAuth)



Encoding for the Key A, register modifier variant

Applies when `(Z == 1 && M == 0)`

```
BLRAA <Xn>, <Xm|SP>
```

Encoding for the Key A, zero modifier variant

Applies when `(Z == 0 && M == 0 && Rm == 11111)`

```
BLRAAZ <Xn>
```

Encoding for the Key B, register modifier variant

Applies when `(Z == 1 && M == 1)`

```
BLRAB <Xn>, <Xm|SP>
```

Encoding for the Key B, zero modifier variant

Applies when `(Z == 0 && M == 1 && Rm == 11111)`

```
BLRABZ <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let use_key_a : boolean = (M == '0');
let source_is_sp : boolean = Z == '1' && m == 31;
let auth_then_branch : boolean = TRUE;
```

Assembler Symbols

<Xn>	Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.
<Xm|SP>	Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

```
var target : bits(64) = X{}(n);
let modifier : bits(64) = if source_is_sp then SP{64}() else X{64}(m);

if use_key_a then
    target = AuthIA(target, modifier, auth_then_branch);
else
    target = AuthIB(target, modifier, auth_then_branch);
end;
if IsFeatureImplemented(FEAT_GCS) && GCSPCREnabled(PSTATE.EL) then
    AddGCSRecord(PC64() + 4);
end;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '10';

X{64}(30) = PC64() + 4;

let branch_conditional : boolean = FALSE;
BranchTo{64}(target, BranchType_INDCALL, branch_conditional);
```

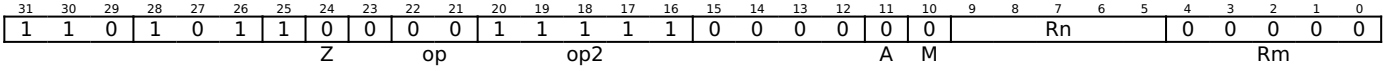
BR

Branch to register

This instruction branches unconditionally to an address in a register. This instruction provides a hint that this is not a subroutine call or return.



Encoding

```
BR <Xn>
```

Decode for this encoding

```
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

```
let target : bits(64) = X{}(n);
// Value in BTypeNext will be used to set PSTATE.BTYPE
if InGuardedPage then
    if n == 16 || n == 17 then
        BTypeNext = '01';
    else
        BTypeNext = '11';
    end;
else
    BTypeNext = '01';
end;

let branch_conditional : boolean = FALSE;
BranchTo{64}(target, BranchType_INDIR, branch_conditional);
```

BRAA, BRAAZ, BRAB, BRABZ

Branch to register, with pointer authentication

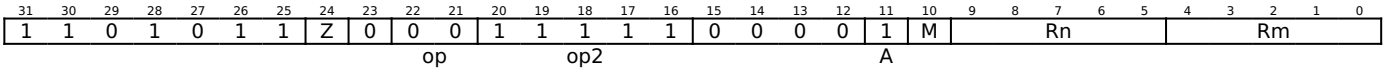
This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and branches to the authenticated address.
The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP>, for BRAA and BRAB.
- The value zero, for BRAAZ and BRABZ.

Key A is used for BRAA and BRAAZ. Key B is used for BRAB and BRABZ.
If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.
The authenticated address is not written back to the general-purpose register.
This instruction provides a hint that this is not a subroutine call or return.

Integer

(FEAT_PAuth)



Encoding for the Key A, register modifier variant

Applies when `(Z == 1 && M == 0)`

```
BRAA <Xn>, <Xm|SP>
```

Encoding for the Key A, zero modifier variant

Applies when `(Z == 0 && M == 0 && Rm == 11111)`

```
BRAAZ <Xn>
```

Encoding for the Key B, register modifier variant

Applies when `(Z == 1 && M == 1)`

```
BRAB <Xn>, <Xm|SP>
```

Encoding for the Key B, zero modifier variant

Applies when `(Z == 0 && M == 1 && Rm == 11111)`

```
BRABZ <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let use_key_a : boolean = (M == '0');
let source_is_sp : boolean = Z == '1' && m == 31;
let auth_then_branch : boolean = TRUE;
```

Assembler Symbols

<Xn>	Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.
<Xm|SP>	Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

```
var target : bits(64) = X{}(n);
let modifier : bits(64) = if source_is_sp then SP{64}() else X{64}(m);

if use_key_a then
    target = AuthIA(target, modifier, auth_then_branch);
else
    target = AuthIB(target, modifier, auth_then_branch);
end;
// Value in BTypeNext will be used to set PSTATE.BTYPE
if InGuardedPage then
    if n == 16 || n == 17 then
        BTypeNext = '01';
    else
        BTypeNext = '11';
    end;
else
    BTypeNext = '01';
end;

let branch_conditional : boolean = FALSE;
BranchTo{64}(target, BranchType_INDIR, branch_conditional);
```

BRB

Branch record buffer

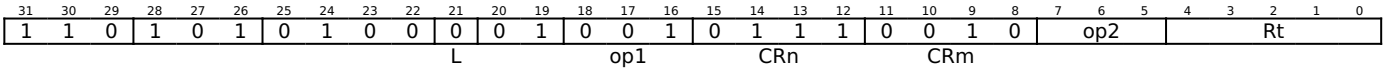
For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions*.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_BRBE)



Encoding

```
BRB <brb_op>
```

is equivalent to

```
SYS #1, C7, C2, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp('001', '0111', '0010', op2) == Sys_BRB`.

Assembler Symbols

<brb_op> Is a BRB operation name, as listed for the BRB system instruction group, encoded in "op2":

op2	<brb_op>	Architectural Feature	Description
100	IALL	FEAT_BRBE	For more information, see BRB IALL.
101	INJ	FEAT_BRBE	For more information, see BRB INJ.

Operation

The description of SYS gives the operational pseudocode for this instruction.

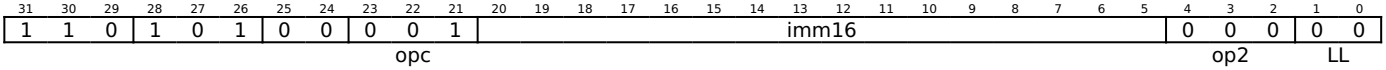
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

BRK

Breakpoint instruction

This instruction generates a Breakpoint Instruction exception. The PE records the exception in *ESR_ELx*, using the EC value 0x3C, and captures the value of the immediate argument in *ESR_ELx*.ISS.

Within a guarded memory region, while *PSTATE*.BTYPE != 0b00, a `BRK` instruction will not generate a Branch Target exception and will generate a Breakpoint Instruction exception as normal. For more information, see *PSTATE.BTYPE*.



Encoding

```
BRK #<imm>
```

Decode for this encoding

```
let comment : bits(16) = imm16;
if IsFeatureImplemented(FEAT_BTI) then
    SetBTypeCompatible(TRUE);
end;
```

Assembler Symbols

<imm>	Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64_SoftwareBreakpoint(comment);
```

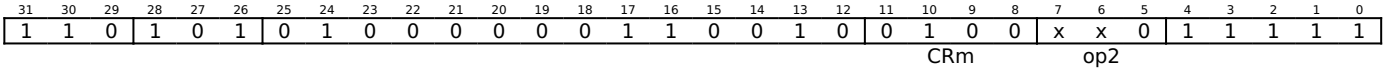
BTI

Branch target identification

This instruction is used to guard against the execution of instructions that are not the intended target of a branch.
Outside of a guarded memory region, a `BTI` instruction executes as a `NOP`. Within a guarded memory region, while *PSTATE*.BTYPE != 0b00, a `BTI` instruction compatible with the current value of PSTATE.BTYPE will not generate a Branch Target Exception and will allow execution of subsequent instructions within the memory region. For more information, see *PSTATE.BTYPE*.
The operand <targets> passed to a `BTI` instruction determines the values of *PSTATE*.BTYPE that the `BTI` instruction is compatible with.

System

(FEAT_BTI)



Encoding

```
BTI {<targets>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_BTI) then EndOfDecode(Decode_NOP); end;

// Check branch target compatibility between BTI instruction and PSTATE.BTYPE
SetBTypeCompatible(BTypeCompatible_BTI(op2[2:1]));
```

Assembler Symbols

<targets> Is the type of indirection, encoded in “op2[2:1]”:

op2[2:1]	<targets>
00	[absent]
01	c
10	j
11	jc

Operation

```
SetBTypeNext('00');
```

CAS, CASA, CASAL, CASL

Compare and swap word or doubleword in memory

This instruction reads a 32-bit word or 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- If the destination register is not one of WZR or XZR, `CASA` and `CASAL` load from memory with acquire semantics.
- `CASL` and `CASAL` store to memory with release semantics.
- `CAS` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, or <Xs>, is restored to the value held in the register before the instruction was executed.

For a `CAS` or `CASA` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent `CAS`, `CASA`, `CASAL`, or `CASL` access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent `CAS`, `CASA`, `CASAL`, or `CASL` access to succeed when it does occur.

A code sequence starting with a `CAS` or `CASA` instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent `CAS`, `CASA`, `CASAL`, or `CASL` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct System register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first `CAS` or `CASA` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CAS` or `CASA` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the `CAS` or `CASA` either fails its compare or writes the same value back to memory.

For performance reasons, Arm recommends that software not use a `CAS` or `CASA` instruction when <Ws> or <Xs> specifies the same register as <Wt> or <Xt> in a routine that includes a subsequent `CAS`, `CASA`, `CASAL`, or `CASL` for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent `CAS`, `CASA`, `CASAL`, or `CASL`.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction that conditionally determines whether or not to execute the subsequent `CAS`, `CASA`, `CASAL`, or `CASL`.

This guidance does not apply when <Ws> or <Xs> specifies the same register as <Wt> or <Xt> for a `CAS` or `CASA` instruction and the compare between the `CAS` or `CASA` and the subsequent `CAS`, `CASA`, `CASAL`, or `CASL` is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent `CAS`, `CASA`, `CASAL`, or `CASL` from executing under normal operating conditions.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

CASB, CASAB, CASALB, CASLB

Compare and swap byte in memory

This instruction reads an 8-bit byte from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- If the destination register is not WZR, `CASAB` and `CASALB` load from memory with acquire semantics.
- `CASLB` and `CASALB` store to memory with release semantics.
- `CASB` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

For a `CASB` or `CASAB` instruction, when <Ws> specifies the same register as <Wt>, this signals to the memory system that an additional subsequent `CASB`, `CASAB`, `CASALB`, or `CASLB` access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent `CASB`, `CASAB`, `CASALB`, or `CASLB` access to succeed when it does occur.

A code sequence starting with a `CASB` or `CASAB` instruction for which <Ws> specifies the same register as <Wt>, and ending with a subsequent `CASB`, `CASAB`, `CASALB`, or `CASLB` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct System register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> of the first `CASB` or `CASAB` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CASB` or `CASAB` instruction, when <Ws> specifies the same register as <Wt>, the value in memory is not modified, because the `CASB` or `CASAB` either fails its compare or writes the same value back to memory.

For performance reasons, Arm recommends that software not use a `CASB` or `CASAB` instruction when <Ws> specifies the same register as <Wt> in a routine that includes a subsequent `CASB`, `CASAB`, `CASALB`, or `CASLB` for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent `CASB`, `CASAB`, `CASALB`, or `CASLB`.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction that conditionally determines whether or not to execute the subsequent `CASB`, `CASAB`, `CASALB`, or `CASLB`.

This guidance does not apply when <Ws> specifies the same register as <Wt> for a `CASB` or `CASAB` instruction and the compare between the `CASB` or `CASAB` and the subsequent `CASB`, `CASAB`, `CASALB`, or `CASLB` is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent `CASB`, `CASAB`, `CASALB`, or `CASLB` from executing under normal operating conditions.

CASH, CASAH, CASALH, CASLH

Compare and swap halfword in memory

This instruction reads a 16-bit halfword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- If the destination register is not WZR, `CASAH` and `CASALH` load from memory with acquire semantics.
- `CASLH` and `CASALH` store to memory with release semantics.
- `CASH` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

For a `CASH` or `CASAH` instruction, when <Ws> specifies the same register as <Wt>, this signals to the memory system that an additional subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` access to succeed when it does occur.

A code sequence starting with a `CASH` or `CASAH` instruction for which <Ws> specifies the same register as <Wt>, and ending with a subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct System register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> of the first `CASH` or `CASAH` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CASH` or `CASAH` instruction, when <Ws> specifies the same register as <Wt>, the value in memory is not modified, because the `CASH` or `CASAH` either fails its compare or writes the same value back to memory.

For performance reasons, Arm recommends that software not use a `CASH` or `CASAH` instruction when <Ws> specifies the same register as <Wt> in a routine that includes a subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH`.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction that conditionally determines whether or not to execute the subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH`.

This guidance does not apply when <Ws> specifies the same register as <Wt> for a `CASH` or `CASAH` instruction and the compare between the `CASH` or `CASAH` and the subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` from executing under normal operating conditions.

CASP, CASPA, CASPAL, CASPL

Compare and swap pair of words or doublewords in memory

This instruction reads a pair of 32-bit words or 64-bit doublewords from memory, and compares them against the values held in the first pair of registers. If the comparison is equal, the values in the second pair of registers are written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the writes are performed, the reads and writes occur atomically such that no other modification of the memory location can take place between the reads and writes.

- `CASPA` and `CASPAL` load from memory with acquire semantics.
- `CASPL` and `CASPAL` store to memory with release semantics.
- `CASP` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the registers which are compared and loaded, that is <Ws> and <W(s+1)>, or <Xs> and <X(s+1)>, are restored to the values held in the registers before the instruction was executed.

For a `CASP` or `CASPA` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` access to succeed when it does occur.

A code sequence starting with a `CASP` or `CASPA` instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct System register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first `CASP` or `CASPA` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CASP` or `CASPA` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the `CASP` or `CASPA` either fails its compare or writes the same value back to memory.

For performance reasons, Arm recommends that software not use a `CASP` or `CASPA` instruction when <Ws> or <Xs> specifies the same register as <Wt> or <Xt> in a routine that includes a subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL`.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction that conditionally determines whether or not to execute the subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL`.

This guidance does not apply when <Ws> or <Xs> specifies the same register as <Wt> or <Xt> for a `CASP` or `CASPA` instruction and the compare between the `CASP` or `CASPA` and the subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` from executing under normal operating conditions.

CASPT, CASPAT, CASPALT, CASPLT

Compare and swap pair unprivileged

This instruction reads a pair of 64-bit doublewords from memory, and compares them against the values held in the first pair of registers. If the comparison is equal, the values in the second pair of registers are written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the writes are performed, the reads and writes occur atomically such that no other modification of the memory location can take place between the reads and writes.

- `CASPAT` and `CASPALT` load from memory with acquire semantics.
- `CASPLT` and `CASPALT` store to memory with release semantics.
- `CASPT` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the registers which are compared and loaded, that is <Xs> and <X(s+1)>, are restored to the values held in the registers before the instruction was executed.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For a `CASPT` or `CASPAT` instruction, when <Xs> specifies the same register as <Xt>, this signals to the memory system that an additional subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` access to succeed when it does occur.

A code sequence starting with a `CASPT` or `CASPAT` instruction for which <Xs> specifies the same register as <Xt>, and ending with a subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct System register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Xs> of the first `CASPT` or `CASPAT` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CASPT` or `CASPAT` instruction, when <Xs> specifies the same register as <Xt>, the value in memory is not modified, because the `CASPT` or `CASPAT` either fails its compare or writes the same value back to memory.

For performance reasons, Arm recommends that software not use a `CASPT` or `CASPAT` instruction when <Xs> specifies the same register as <Xt> in a routine that includes a subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT`.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction that conditionally determines whether or not to execute the subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT`.

This guidance does not apply when <Xs> specifies the same register as <Xt> for a `CASPT` or `CASPAT` instruction and the compare between the `CASPT` or `CASPAT` and the subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` from executing under normal operating conditions.

CAST, CASAT, CASALT, CASLT

Compare and swap unprivileged

This instruction reads a 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- If the destination register is not XZR, `CASAT` and `CASALT` load from memory with acquire semantics.
- `CASLT` and `CASALT` store to memory with release semantics.
- `CAST` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Xs>, is restored to the value held in the register before the instruction was executed.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For a `CAST` or `CASAT` instruction, when <Xs> specifies the same register as <Xt>, this signals to the memory system that an additional subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` access to succeed when it does occur.

A code sequence starting with a `CAST` or `CASAT` instruction for which <Xs> specifies the same register as <Xt>, and ending with a subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct System register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Xs> of the first `CAST` or `CASAT` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CAST` or `CASAT` instruction, when <Xs> specifies the same register as <Xt>, the value in memory is not modified, because the `CAST` or `CASAT` either fails its compare or writes the same value back to memory.

For performance reasons, Arm recommends that software not use a `CAST` or `CASAT` instruction when <Xs> specifies the same register as <Xt> in a routine that includes a subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT`.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction that conditionally determines whether or not to execute the subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT`.

This guidance does not apply when <Xs> specifies the same register as <Xt> for a `CAST` or `CASAT` instruction and the compare between the `CAST` or `CASAT` and the subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` from executing under normal operating conditions.

CBB<cc>

Compare bytes and branch

This instruction compares the byte values in two registers, and conditionally branches to a label at a PC-relative offset if the condition is true. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.

This instruction is used by the pseudo-instructions CBBLE, CBBLO, CBBLS, and CBBLT.

Branch

CBBLE

Compare signed less than or equal to bytes and branch

This instruction compares the signed byte values in two registers, and conditionally branches to a label at a PC-relative offset if the second value is less than or equal to the first. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.

This is a pseudo-instruction of CBB<cc>. This means:

- The encodings in this description are named to match the encodings of CBB<cc>.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CBB<cc> gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Encoding for the 32-bit less than variant

Applies when `(sf == 0)`

```
CBLE <Wt>, #<imms1>, <label>
```

is equivalent to

```
CBLT <Wt>, #<imm>, <label>
```

Encoding for the 64-bit less than variant

Applies when `(sf == 1)`

```
CBLE <Xt>, #<imms1>, <label>
```

is equivalent to

```
CBLT <Xt>, #<imm>, <label>
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<imms1>	Is a signed immediate, in the range -1 to 62, encoded as "imm6" minus 1.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range -1024 to 1020, is encoded as "imm9" times 4.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

Operation

The description of CB<cc> (immediate) gives the operational pseudocode for this instruction.

CBLE (register)

Compare signed less than or equal to register and branch

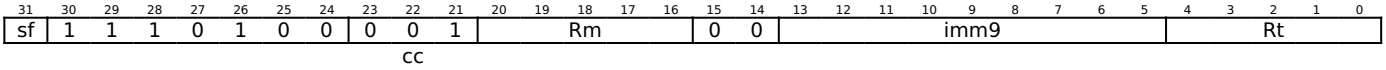
This instruction compares the signed values in two registers, and conditionally branches to a label at a PC-relative offset if the second value is less than or equal to the first. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.

This is a pseudo-instruction of CB<cc> (register). This means:

- The encodings in this description are named to match the encodings of CB<cc> (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CB<cc> (register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Branch

(FEAT_CMPBR)



Encoding for the 32-bit greater than or equal variant

Applies when `(sf == 0)`

```
CBLE <Wm>, <Wt>, <label>
```

is equivalent to

```
CBGE <Wt>, <Wm>, <label>
```

Encoding for the 64-bit greater than or equal variant

Applies when `(sf == 1)`

```
CBLE <Xm>, <Xt>, <label>
```

is equivalent to

```
CBGE <Xt>, <Xm>, <label>
```

Assembler Symbols

<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range -1024 to 1020, is encoded as "imm9" times 4.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

Operation

The description of CB<cc> (register) gives the operational pseudocode for this instruction.

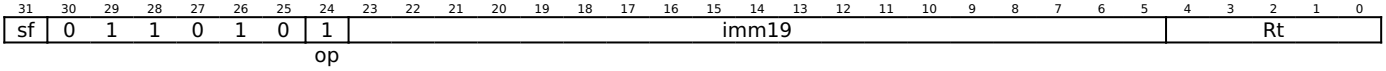
CBNZ

Compare and branch on nonzero

This instruction compares the value in a register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CBNZ <Wt>, <label>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CBNZ <Xt>, <label>
```

Decode for all variants of this encoding

```
let t : integer = UInt(Rt);
let datasize : integer{} = 32 << UInt(sf);
let offset : bits(64) = SignExtend{}(imm19::'00');
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

Operation

```
let branch_conditional : boolean = TRUE;
let operand1 : bits(datasize) = X{datasize}(t);
if !IsZero(operand1) then
    BranchTo{64}(PC64() + offset, BranchType_DIR, branch_conditional);
else
    BranchNotTaken(BranchType_DIR, branch_conditional);
end;
```

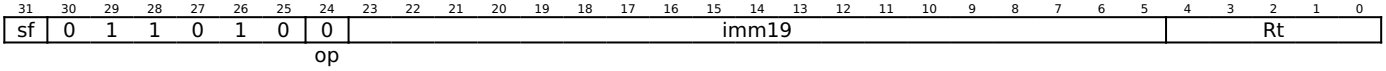
CBZ

Compare and branch on zero

This instruction compares the value in a register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CBZ <Wt>, <label>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CBZ <Xt>, <label>
```

Decode for all variants of this encoding

```
let t : integer = UInt(Rt);
let datasize : integer{} = 32 << UInt(sf);
let offset : bits(64) = SignExtend{}(imm19::'00');
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

Operation

```
let branch_conditional : boolean = TRUE;
let operand1 : bits(datasize) = X{datasize}(t);
if IsZero(operand1) then
    BranchTo{64}(PC64() + offset, BranchType_DIR, branch_conditional);
else
    BranchNotTaken(BranchType_DIR, branch_conditional);
end;
```

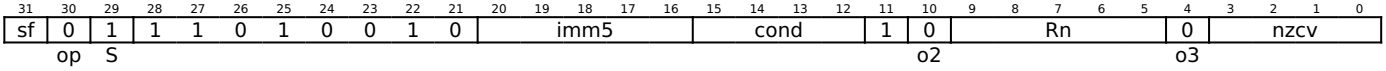
CCMN (immediate)

Conditional compare negative (immediate)

This instruction sets the value of the condition flags to the result of the comparison of a register value and a negated immediate value if the condition is TRUE, and an immediate value otherwise.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CCMN <Wn>, #<imm>, #<nzcv>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CCMN <Xn>, #<imm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
var flags : bits(4) = nzcv;
let imm : bits(datasize) = ZeroExtend{}(imm5);
```

Assembler Symbols

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<imm> Is a five bit unsigned (positive) immediate encoded in the "imm5" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
if ConditionHolds(condition) then
    let operand1 : bits(datasize) = X{datasize}(n);
    let operand2 : bits(datasize) = imm;

    (-, flags) = AddWithCarry{datasize}(operand1, operand2, '0');
end;
PSTATE.[N,Z,C,V] = flags;
```

Operational information

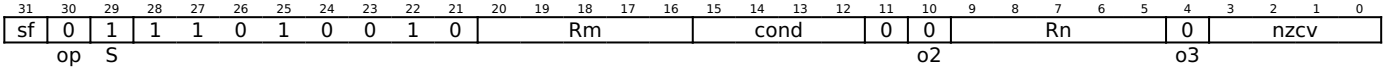
This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

CCMN (register)

Conditional compare negative (register)

This instruction sets the value of the condition flags to the result of the comparison of a register value and the inverse of another register value if the condition is TRUE, and an immediate value otherwise.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CCMN <Wn>, <Wm>, #<nzcv>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CCMN <Xn>, <Xm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
var flags : bits(4) = nzcv;
```

Assembler Symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionHolds(condition) then
    let operand1 : bits(datasize) = X{datasize}(n);
    let operand2 : bits(datasize) = X{datasize}(m);

    (-, flags) = AddWithCarry{datasize}(operand1, operand2, '0');
end;
PSTATE.[N,Z,C,V] = flags;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

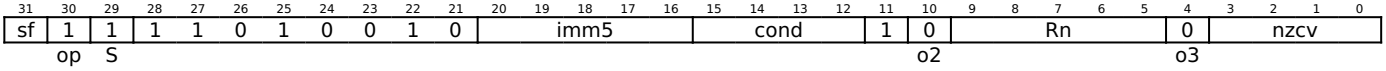
CCMP (immediate)

Conditional compare (immediate)

This instruction sets the value of the condition flags to the result of the comparison of a register value and an immediate value if the condition is TRUE, and an immediate value otherwise.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CCMP <Wn>, #<imm>, #<nzcv>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CCMP <Xn>, #<imm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
var flags : bits(4) = nzcv;
let imm : bits(datasize) = ZeroExtend{}(imm5);
```

Assembler Symbols

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<imm> Is a five bit unsigned (positive) immediate encoded in the "imm5" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
if ConditionHolds(condition) then
    let operand1 : bits(datasize) = X{datasize}(n);
    let operand2 : bits(datasize) = imm;

    (-, flags) = AddWithCarry{datasize}(operand1, NOT operand2, '1');
end;
PSTATE.[N,Z,C,V] = flags;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

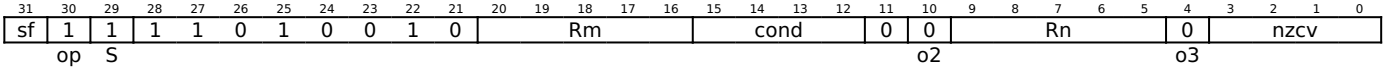
CCMP (register)

Conditional compare (register)

This instruction sets the value of the condition flags to the result of the comparison of two registers if the condition is TRUE, and an immediate value otherwise.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CCMP <Wn>, <Wm>, #<nzcv>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CCMP <Xn>, <Xm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
var flags : bits(4) = nzcv;
```

Assembler Symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>

1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionHolds(condition) then
    let operand1 : bits(datasize) = X{datasize}(n);
    let operand2 : bits(datasize) = X{datasize}(m);

    (-, flags) = AddWithCarry{datasize}(operand1, NOT operand2, '1');
end;
PSTATE.[N,Z,C,V] = flags;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

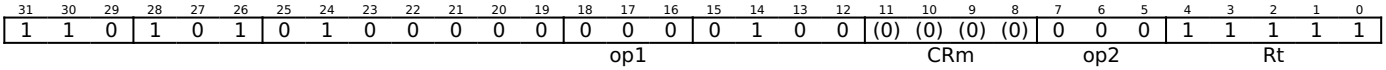
CFINV

Invert carry flag

This instruction inverts the value of the PSTATE.C flag.

System

(FEAT_FlagM)



Encoding

```
CFINV
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_FlagM) then EndOfDecode(Decode_UNDEF); end;
```

Operation

```
PSTATE.C = NOT PSTATE.C;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

CFLT<cc> (immediate)

Compare register with immediate and fault

This instruction compares the value in a register with an immediate, and generates a Conditional fault exception if the comparison is true. If an exception is generated, the <reason> operand is copied to *ESR_ELx*.

This instruction does not affect the condition flags.

This instruction is used by the pseudo-instructions CFLTGE (immediate), CFLTHS (immediate), CFLTLE (immediate), CFLTLS (immediate), CFLTNZ, and CFLTZ.

Fault

(FEAT_CFLT)

Encoding for the 32-bit greater than variant

Applies when `(sf == 0 && cc == 000)`

```
CFLTGT #<reason>, <Wt>, #<imm>
```

Encoding for the 32-bit less than variant

Applies when `(sf == 0 && cc == 001)`

CFLT<cc> (register)

Compare registers and fault

This instruction compares the values in two registers, and generates a Conditional fault exception if the condition is true. This instruction does not affect the condition flags.

This instruction is used by the pseudo-instructions CFLTLE (register), CFLTLO (register), CFLTLS (register), and CFLTLT (register).

Fault

(FEAT_CFLT)

Encoding for the 32-bit greater than variant

Applies when `(sf == 0 && cc == 000)`

```
CFLTGT #<reason>, <Wt|WSP>, <Wm|WSP>
```

Encoding for the 32-bit greater than or equal variant

Applies when `(sf == 0 && cc == 001)`

```
CFLTGE #<reason>, <Wt|WSP>, <Wm|WSP>
```

Encoding for the 32-bit higher variant

Applies when `(sf == 0 && cc == 010)`

```
CFLTHI #<reason>, <Wt|WSP>, <Wm|WSP>
```

Encoding for the 32-bit higher or same variant

Applies when `(sf == 0 && cc == 011)`

```
CFLTHS #<reason>, <Wt|WSP>, <Wm|WSP>
```

Encoding for the 32-bit equal variant

Applies when `(sf == 0 && cc == 110)`

```

CFLTGE (immediate)

Compare signed greater than or equal to immediate and fault

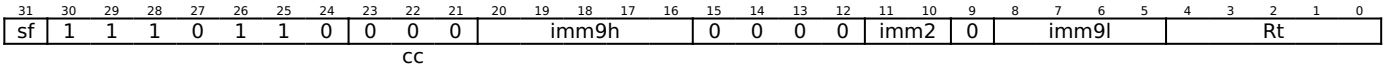
This instruction compares the signed value in a register with an immediate, and generates a Conditional fault exception if the register value is greater than or equal to the immediate. If an exception is generated, the <reason> operand is copied to *ESR_ELx*.
This instruction does not affect the condition flags.

This is a pseudo-instruction of CFLT<cc> (immediate). This means:

- The encodings in this description are named to match the encodings of CFLT<cc> (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CFLT<cc> (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Fault

(FEAT_CFLT)



Encoding for the 32-bit greater than variant

Applies when `(sf == 0)`

```
CFLTGE #<reason>, <Wt>, #<immp1>
```

is equivalent to

```
CFLTGT #<reason>, <Wt>, #<imm>
```

Encoding for the 64-bit greater than variant

Applies when `(sf == 1)`

```
CFLTGE #<reason>, <Xt>, #<immp1>
```

is equivalent to

```
CFLTGT #<reason>, <Xt>, #<imm>
```

Assembler Symbols

<reason>	Is a 2-bit unsigned immediate, in the range 0 to 3, encoded in the "imm2" field.
<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<immp1>	Is a signed immediate, in the range -255 to 256, encoded as "imm9h:imm9l" plus 1.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

Operation

The description of CFLT<cc> (immediate) gives the operational pseudocode for this instruction.

CFLTLO (register)

Compare registers and fault if lower

This instruction compares the values in two registers, and generates a Conditional fault exception if the first value is lower than the second. If an exception is generated, the <reason> operand is copied to *ESR_ELx*.
This instruction does not affect the condition flags.

This is a pseudo-instruction of CFLT<cc> (register). This means:

- The encodings in this description are named to match the encodings of CFLT<cc> (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CFLT<cc> (register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

CFP

Control flow prediction restriction by context

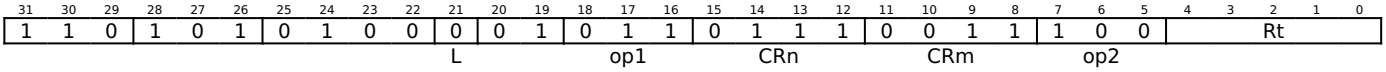
This instruction prevents control flow predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.
For more information, see CFP RCTX, Control Flow Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SPECRES)



Encoding

```
CFP RCTX, <Xt>
```

is equivalent to

```
SYS #3, C7, C3, #4, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

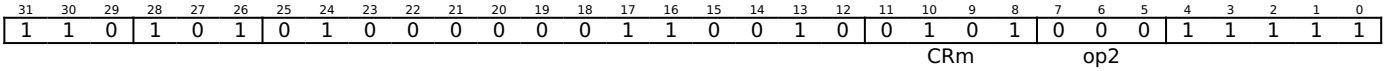
CHKFEAT

Check feature status

This instruction indicates the status of features. For more information, see *Check Feature*.
If *FEAT_CHK* is not implemented, this instruction executes as a `NOP`.

System

(FEAT_CHK)



Encoding

```
CHKFEAT X16
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CHK) then EndOfDecode(Decode_NOP); end;
```

Operation

```
X{64}(16) = AArch64_ChkFeat(X{64}(16));
```

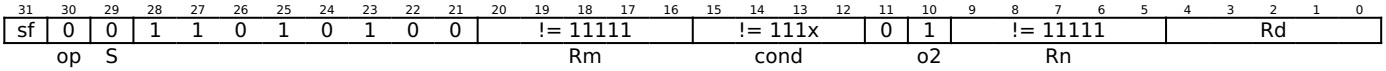
CINC

Conditional increment

This instruction returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINC. This means:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CINC <Wd>, <Wn>, <invcond>
```

is equivalent to

```
CSINC <Wd>, <Wn>, <Wm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CINC <Xd>, <Xn>, <invcond>
```

is equivalent to

```
CSINC <Xd>, <Xn>, <Xm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<invcond> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in “cond”:

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC|LO	Maps to <cond> CS.
0011	CS|HS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.
0110	VC	Maps to <cond> VS.
0111	VS	Maps to <cond> VC.
1000	LS	Maps to <cond> HI.
1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational Information

The description of CSINC gives the operational information for this instruction.

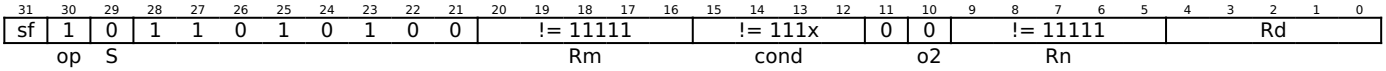
CINV

Conditional invert

This instruction returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CINV <Wd>, <Wn>, <invcond>
```

is equivalent to

```
CSINV <Wd>, <Wn>, <Wm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CINV <Xd>, <Xn>, <invcond>
```

is equivalent to

```
CSINV <Xd>, <Xn>, <Xm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<invcond> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in “cond”:

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC|LO	Maps to <cond> CS.
0011	CS|HS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.
0110	VC	Maps to <cond> VS.
0111	VS	Maps to <cond> VC.
1000	LS	Maps to <cond> HI.
1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

Operational Information

The description of CSINV gives the operational information for this instruction.

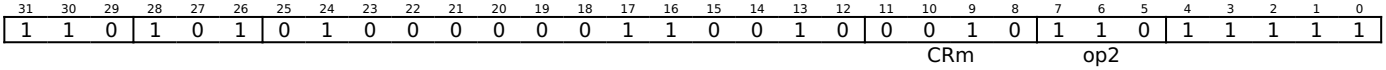
CLRBHB

Clear branch history

This instruction can be used to clear the branch history.
For more information, see *Branch history*.

System

(FEAT_CLRBHB)



Encoding

CLRBHB

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CLRBHB) then EndOfDecode(Decode_NOP); end;
```

Operation

```
Hint_CLRBHB();
```

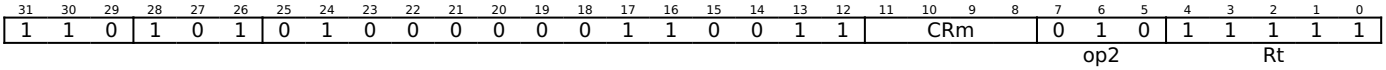
CLREX

Clear exclusive

This instruction clears the local monitor of the executing PE.



Encoding

```
CLREX {#<imm>}
```

Decode for this encoding

```
// CRm field is ignored
```

Assembler Symbols

<imm>	Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

Operation

```
ClearExclusiveLocal(ProcessorID());
```

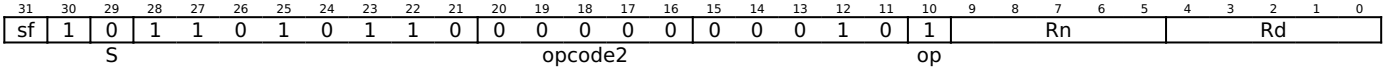
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

CLS

Count leading sign bits

This instruction determines the number of leading bits of the source register that have the same value as the most significant bit of the register, and writes the result to the destination register. The result does not include the most significant bit of the source register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CLS <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CLS <Xd>, <Xn>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = CountLeadingSignBits(operand1);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

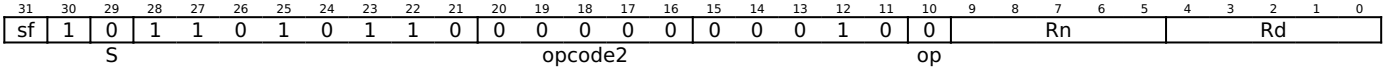
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

CLZ

Count leading zeros

This instruction determines the number of consecutive binary zero bits, starting from the most significant bit in the source register, and places the result in the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CLZ <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CLZ <Xd>, <Xn>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = CountLeadingZeroBits(operand1);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

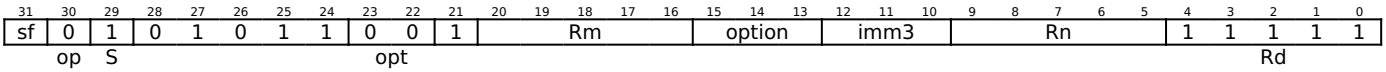
CMN (extended register)

Compare negative (extended register)

This instruction adds a register value and a sign-extended or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (extended register). This means:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

is equivalent to

```
ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

is equivalent to

```
ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Operation

The description of ADDS (extended register) gives the operational pseudocode for this instruction.

Operational Information

The description of ADDS (extended register) gives the operational information for this instruction.

2026-09_rel 2026-09-21 14:22:38

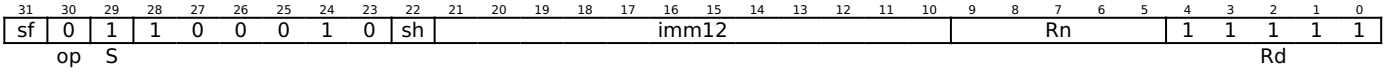
CMN (immediate)

Compare negative (immediate)

This instruction adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (immediate). This means:

- The encodings in this description are named to match the encodings of ADDS (immediate).
- The description of ADDS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CMN <Wn|WSP>, #<imm>{, <shift>}
```

is equivalent to

```
ADDS WZR, <Wn|WSP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CMN <Xn|SP>, #<imm>{, <shift>}
```

is equivalent to

```
ADDS XZR, <Xn|SP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ADDS (immediate) gives the operational information for this instruction.

2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

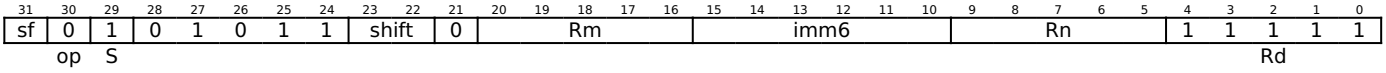
CMN (shifted register)

Compare negative (shifted register)

This instruction adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CMN <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CMN <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ADDS (shifted register) gives the operational information for this instruction.

2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

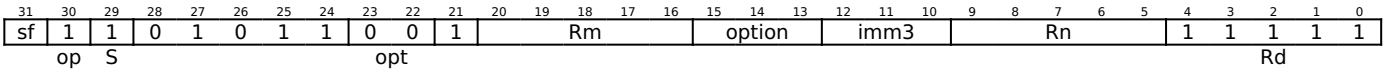
CMP (extended register)

Compare (extended register)

This instruction subtracts a sign-extended or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (extended register). This means:

- The encodings in this description are named to match the encodings of SUBS (extended register).
- The description of SUBS (extended register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

is equivalent to

```
SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

is equivalent to

```
SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Operation

The description of SUBS (extended register) gives the operational pseudocode for this instruction.

Operational Information

The description of SUBS (extended register) gives the operational information for this instruction.

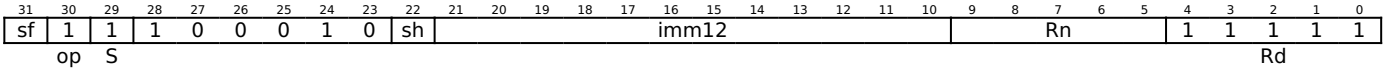
CMP (immediate)

Compare (immediate)

This instruction subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (immediate). This means:

- The encodings in this description are named to match the encodings of SUBS (immediate).
- The description of SUBS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CMP <Wn|WSP>, #<imm>{, <shift>}
```

is equivalent to

```
SUBS WZR, <Wn|WSP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CMP <Xn|SP>, #<imm>{, <shift>}
```

is equivalent to

```
SUBS XZR, <Xn|SP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of SUBS (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of SUBS (immediate) gives the operational information for this instruction.

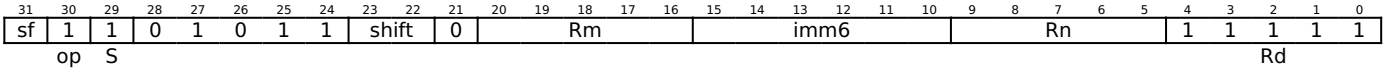
CMP (shifted register)

Compare (shifted register)

This instruction subtracts an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CMP <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CMP <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of SUBS (shifted register) gives the operational information for this instruction.

CMPP

Compare with tag

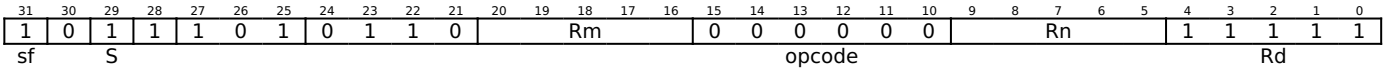
This instruction subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, updates the condition flags based on the result of the subtraction, and discards the result.

This is an alias of SUBPS. This means:

- The encodings in this description are named to match the encodings of SUBPS.
- The description of SUBPS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_MTE)



Encoding

```
CMPP <Xn|SP>, <Xm|SP>
```

is equivalent to

```
SUBPS XZR, <Xn|SP>, <Xm|SP>
```

and is always the preferred disassembly.

Assembler Symbols

<Xn|SP>	Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xm|SP>	Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Operation

The description of SUBPS gives the operational pseudocode for this instruction.

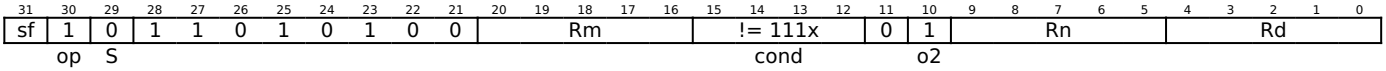
CNEG

Conditional negate

This instruction returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSNEG. This means:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CNEG <Wd>, <Wn>, <invcond>
```

is equivalent to

```
CSNEG <Wd>, <Wn>, <Wm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CNEG <Xd>, <Xn>, <invcond>
```

is equivalent to

```
CSNEG <Xd>, <Xn>, <Xm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<invcond> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in “cond”:

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC|LO	Maps to <cond> CS.
0011	CS|HS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.
0110	VC	Maps to <cond> VS.
0111	VS	Maps to <cond> VC.
1000	LS	Maps to <cond> HI.
1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.

Operational Information

The description of CSNEG gives the operational information for this instruction.

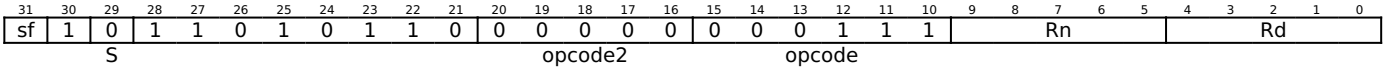
CNT

Count bits

This instruction determines the number of binary one bits in the value of the source register, and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CNT <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CNT <Xd>, <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let datasize : integer{} = 32 << UInt(sf);
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = BitCount(operand1);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

COSP

Clear other speculative prediction restriction by context

This instruction prevents predictions, other than Cache prefetch, Control flow, and Data Value predictions, that predict execution addresses based on information gathered from earlier execution within a particular execution context. Predictions, other than Cache prefetch, Control flow, and Data Value predictions, determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control any speculative access occurring after the instruction is complete and synchronized.

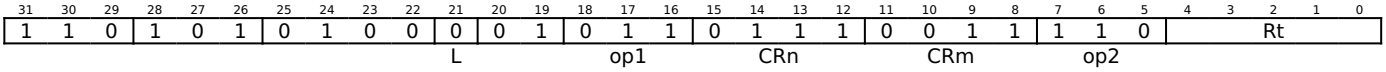
For more information, see COSP RCTX, Clear Other Speculative Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SPECRES2)



Encoding

```
COSP RCTX, <Xt>
```

is equivalent to

```
SYS #3, C7, C3, #6, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

CPYFP, CPYFM, CPYFE

Memory copy forward-only

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFP, then CPYFM, and then CPYFE.
CPYFP performs some preconditioning of the arguments suitable for using the CPYFM instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFM copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFE copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFP:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFP, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFP, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFM, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFM, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.

For CPYFE, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

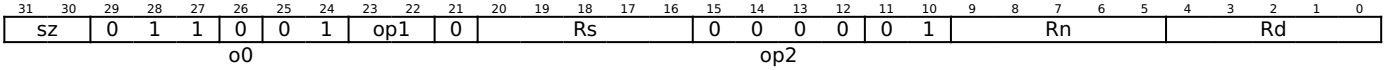
For CPYFE, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYFP [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

CPYFPN, CPYFMN, CPYFEN

Memory copy forward-only, reads and writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPN, then CPYFMN, and then CPYFEN.
CPYFPN performs some preconditioning of the arguments suitable for using the CPYFMN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFEN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFEN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFEN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

CPYFPRN, CPYFMRN, CPYFERN

Memory copy forward-only, reads non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRN, then CPYFMRN, and then CPYFERN.
CPYFPRN performs some preconditioning of the arguments suitable for using the CPYFMRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFERN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPRN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPRN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPRN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMRN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMRN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFERN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFERN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

CPYFPRT, CPYFMRT, CPYFERT

Memory copy forward-only, reads unprivileged

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRT, then CPYFMRT, and then CPYFERT.
CPYFPRT performs some preconditioning of the arguments suitable for using the CPYFMRT instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMRT copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFERT copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPRT:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPRT, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPRT, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMRT, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMRT, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFERT, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFERT, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

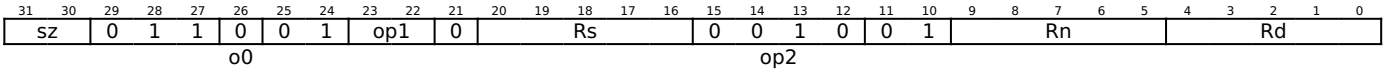
Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

CPYFPRTN, CPYFMRTN, CPYFERTN

Memory copy forward-only, reads unprivileged, reads and writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTN, then CPYFMRTN, and then CPYFERTN.
CPYFPRTN performs some preconditioning of the arguments suitable for using the CPYFMRTN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMRTN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFERTN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPRTN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPRTN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPRTN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMRTN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMRTN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFERTN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFERTN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

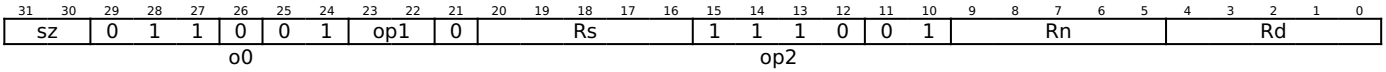
Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYFPRTN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYFMRTN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYFERTN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

CPYFPRTRN, CPYFMRTRN, CPYFERTRN

Memory copy forward-only, reads unprivileged and non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTRN, then CPYFMRTRN, and then CPYFERTRN.
CPYFPRTRN performs some preconditioning of the arguments suitable for using the CPYFMRTRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMRTRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFERTRN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPRTRN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPRTRN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPRTRN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMRTRN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMRTRN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFERTRN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFERTRN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPRTWN, CPYFMRTWN, CPYFERTWN

Memory copy forward-only, reads unprivileged, writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTWN, then CPYFMRTWN, and then CPYFERTWN.
CPYFPRTWN performs some preconditioning of the arguments suitable for using the CPYFMRTWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMRTWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFERTWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPRTWN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPRTWN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPRTWN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMRTWN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMRTWN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFERTWN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFERTWN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

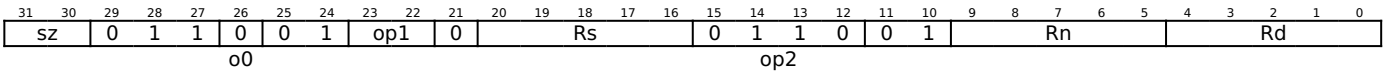
Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYFPRTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYFMRTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYFERTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

CPYFPT, CPYFMT, CPYFET

Memory copy forward-only, reads and writes unprivileged

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPT, then CPYFMT, and then CPYFET.
CPYFPT performs some preconditioning of the arguments suitable for using the CPYFMT instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMT copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFET copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPT:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPT, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPT, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMT, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMT, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.

For CPYFET, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFET, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPTN, CPYFMTN, CPYFETN

Memory copy forward-only, reads and writes unprivileged and non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTN, then CPYFMTN, and then CPYFETN.
CPYFPTN performs some preconditioning of the arguments suitable for using the CPYFMTN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMTN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFETN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPTN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPTN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPTN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMTN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMTN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.

For CPYFETN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFETN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

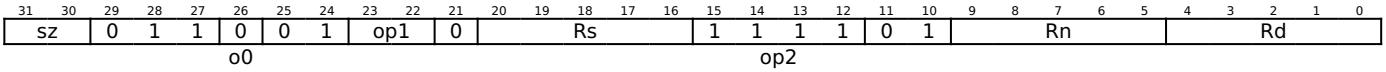
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYFPTN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYFMTN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYFETN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

CPYFPTRN, CPYFMTRN, CPYFETRN

Memory copy forward-only, reads and writes unprivileged, reads non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTRN, then CPYFMTRN, and then CPYFETRN.
CPYFPTRN performs some preconditioning of the arguments suitable for using the CPYFMTRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMTRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFETRN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPTRN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPTRN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPTRN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMTRN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMTRN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.

For CPYFETRN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFETRN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPTWN, CPYFMTWN, CPYFETWN

Memory copy forward-only, reads and writes unprivileged, writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTWN, then CPYFMTWN, and then CPYFETWN.
CPYFPTWN performs some preconditioning of the arguments suitable for using the CPYFMTWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMTWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFETWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPTWN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPTWN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPTWN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMTWN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMTWN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFETWN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFETWN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

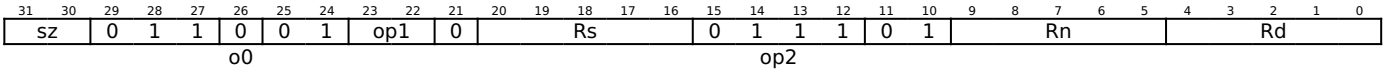
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYFPTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYFMTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYFETWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

CPYFPWN, CPYFMWN, CPYFEWN

Memory copy forward-only, writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWN, then CPYFMWN, and then CPYFEWN.
CPYFPWN performs some preconditioning of the arguments suitable for using the CPYFMWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFEWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPWN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPWN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPWN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMWN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMWN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFEWN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFEWN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

CPYFPWT, CPYFMWT, CPYFEWT

Memory copy forward-only, writes unprivileged

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWT, then CPYFMWT, and then CPYFEWT.
CPYFPWT performs some preconditioning of the arguments suitable for using the CPYFMWT instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMWT copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFEWT copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPWT:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPWT, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPWT, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMWT, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMWT, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the lowest address that has not been copied from.
    - Xd holds the lowest address that has not been copied to.

For CPYFEWT, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFEWT, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPWTN, CPYFMWTN, CPYFEWTN

Memory copy forward-only, writes unprivileged, reads and writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTN, then CPYFMWTN, and then CPYFEWTN.
CPYFPWTN performs some preconditioning of the arguments suitable for using the CPYFMWTN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMWTN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFEWTN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPWTN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPWTN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPWTN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMWTN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMWTN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFEWTN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFEWTN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPWTRN, CPYFMWTRN, CPYFEWTRN

Memory copy forward-only, writes unprivileged, reads non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTRN, then CPYFMWTRN, and then CPYFEWTRN.
CPYFPWTRN performs some preconditioning of the arguments suitable for using the CPYFMWTRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMWTRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFEWTRN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPWTRN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPWTRN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPWTRN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMWTRN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMWTRN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFEWTRN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFEWTRN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPWTWN, CPYFMWTWN, CPYFEWTWN

Memory copy forward-only, writes unprivileged and non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address in a forward direction. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTWN, then CPYFMWTWN, and then CPYFEWTWN.
CPYFPWTWN performs some preconditioning of the arguments suitable for using the CPYFMWTWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYFMWTWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYFEWTWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than or equal to the destination address.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYFPWTWN:

- If Xn[63] == '1', the copy size is saturated to 0x7FFFFFFFFFFFFFF.

On completion of CPYFPWTWN, option A:

- Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the original Xs + saturated copy size.
- Xd holds the original Xd + saturated copy size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of CPYFPWTWN, option B:

- Xn holds the number of bytes in the saturated copy size remaining to be copied.
- Xs holds the lowest address that has not been copied from.
- Xd holds the lowest address that has not been copied to.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For CPYFMWTWN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.

For CPYFMWTWN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

For CPYFEWTWN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from - Xn.
- Xd holds the lowest address to be copied to - Xn.
- On completion of the instruction, Xn holds 0.

For CPYFEWTWN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be copied.
- Xs holds the lowest address to be copied from.
- Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds 0.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

CPYP, CPYM, CPYE

Memory copy

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYP, then CPYM, and then CPYE.

CPYP performs some preconditioning of the arguments suitable for using the CPYM instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYM copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYE copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYP:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYP, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYP, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYM, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYM, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.

- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYE, option A, when PSTATE.C = 0:

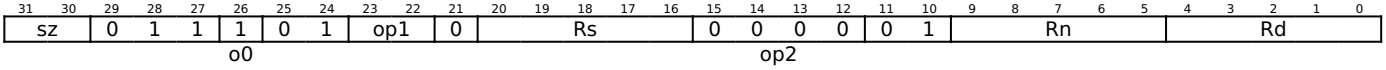
- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYE, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYP [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYM [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYE [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

CPYPN, CPYMN, CPYEN

Memory copy, reads and writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPN, then CPYMN, and then CPYEN.
CPYPN performs some preconditioning of the arguments suitable for using the CPYMN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

        - Xd holds the lowest address to be copied to.
        - On completion of the instruction:
            - Xn holds the number of bytes remaining to be copied.
            - Xs holds the lowest address that has not been copied from.
            - Xd holds the lowest address that has not been copied to.
    - If the copy is in the backward direction (PSTATE.N == 1), then:
        - Xs holds the highest address to be copied from + 1.
        - Xd holds the highest address to be copied to + 1.
        - On completion of the instruction:
            - Xn holds the number of bytes remaining to be copied.
            - Xs holds the highest address that has not been copied from + 1.
            - Xd holds the highest address that has not been copied to + 1.

For CPYEN, option A, when PSTATE.C = 0:

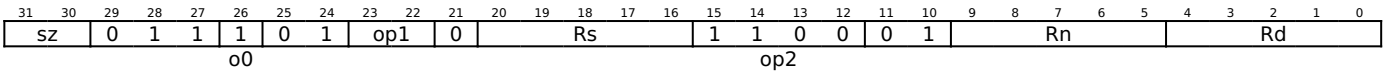
- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

For CPYEN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address to be copied from.
    - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address to be copied from + 1.
    - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYEN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```

CPYPRN, CPYMRN, CPYERN

Memory copy, reads non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRN, then CPYMRN, and then CPYERN.
CPYPRN performs some preconditioning of the arguments suitable for using the CPYMRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYERN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPRN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPRN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPRN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYERN, option A, when PSTATE.C = 0:

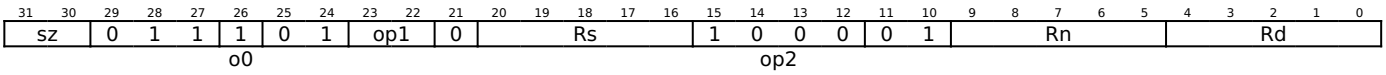
- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYERN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPRN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMRN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYERN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *Memory Copy and Memory Set CPY** and *Crossing a page boundary with different memory types or Shareability attributes*.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the "Rn" field.

CPYPRT, CPYMRT, CPYERT

Memory copy, reads unprivileged

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRT, then CPYMRT, and then CPYERT.
CPYPRT performs some preconditioning of the arguments suitable for using the CPYMRT instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMRT copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYERT copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPRT:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPRT, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPRT, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMRT, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMRT, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYERT, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYERT, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

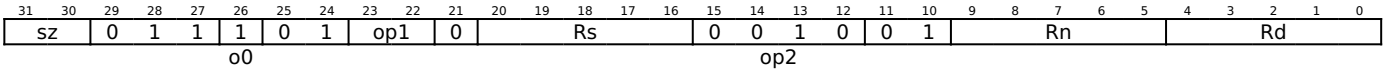
Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPRT [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMRT [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYERT [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *Memory Copy and Memory Set CPY** and *Crossing a page boundary with different memory types or Shareability attributes*.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the "Rn" field.

CPYPRTN, CPYMRTN, CPYERTN

Memory copy, reads unprivileged, reads and writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTN, then CPYMRTN, and then CPYERTN.
CPYPRTN performs some preconditioning of the arguments suitable for using the CPYMRTN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMRTN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYERTN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPRTN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPRTN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPRTN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMRTN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMRTN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

        - Xd holds the lowest address to be copied to.
        - On completion of the instruction:
            - Xn holds the number of bytes remaining to be copied.
            - Xs holds the lowest address that has not been copied from.
            - Xd holds the lowest address that has not been copied to.
    - If the copy is in the backward direction (PSTATE.N == 1), then:
        - Xs holds the highest address to be copied from + 1.
        - Xd holds the highest address to be copied to + 1.
        - On completion of the instruction:
            - Xn holds the number of bytes remaining to be copied.
            - Xs holds the highest address that has not been copied from + 1.
            - Xd holds the highest address that has not been copied to + 1.

For CPYERTN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

For CPYERTN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address to be copied from.
    - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address to be copied from + 1.
    - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

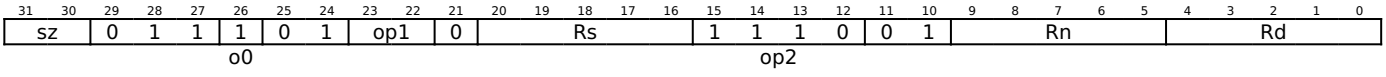
Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPRTN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```

CPYPRTRN, CPYMRTRN, CPYERTRN

Memory copy, reads unprivileged and non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTRN, then CPYMRTRN, and then CPYERTRN.
CPYPRTRN performs some preconditioning of the arguments suitable for using the CPYMRTRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMRTRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYERTRN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPRTRN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPRTRN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPRTRN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMRTRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMRTRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYERTRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYERTRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYPRTWN, CPYMRTWN, CPYERTWN

Memory copy, reads unprivileged, writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTWN, then CPYMRTWN, and then CPYERTWN.
CPYPRTWN performs some preconditioning of the arguments suitable for using the CPYMRTWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMRTWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYERTWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPRTWN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPRTWN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPRTWN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMRTWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMRTWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYERTWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYERTWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

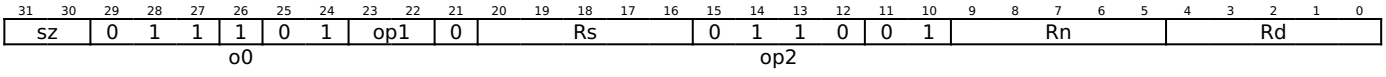
Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPRTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMRTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYERTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *Memory Copy and Memory Set CPY** and *Crossing a page boundary with different memory types or Shareability attributes*.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the "Rn" field.

CPYPT, CPYMT, CPYET

Memory copy, reads and writes unprivileged

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPT, then CPYMT, and then CPYET.
CPYPT performs some preconditioning of the arguments suitable for using the CPYMT instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMT copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYET copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPT:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPT, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPT, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMT, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMT, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYET, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYET, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

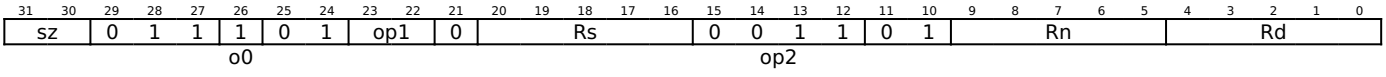
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPT [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMT [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYET [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *Memory Copy and Memory Set CPY** and *Crossing a page boundary with different memory types or Shareability attributes*.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the "Rn" field.

CPYPTN, CPYMTN, CPYETN

Memory copy, reads and writes unprivileged and non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTN, then CPYMTN, and then CPYETN.
CPYPTN performs some preconditioning of the arguments suitable for using the CPYMTN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMTN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYETN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPTN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPTN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPTN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMTN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMTN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYETN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYETN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYPTRN, CPYMTRN, CPYETRN

Memory copy, reads and writes unprivileged, reads non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTRN, then CPYMTRN, and then CPYETRN.
CPYPTRN performs some preconditioning of the arguments suitable for using the CPYMTRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMTRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYETRN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPTRN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPTRN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPTRN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMTRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMTRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

        - Xd holds the lowest address to be copied to.
        - On completion of the instruction:
            - Xn holds the number of bytes remaining to be copied.
            - Xs holds the lowest address that has not been copied from.
            - Xd holds the lowest address that has not been copied to.
    - If the copy is in the backward direction (PSTATE.N == 1), then:
        - Xs holds the highest address to be copied from + 1.
        - Xd holds the highest address to be copied to + 1.
        - On completion of the instruction:
            - Xn holds the number of bytes remaining to be copied.
            - Xs holds the highest address that has not been copied from + 1.
            - Xd holds the highest address that has not been copied to + 1.

For CPYETRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

For CPYETRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address to be copied from.
    - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address to be copied from + 1.
    - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYPTWN, CPYMTWN, CPYETWN

Memory copy, reads and writes unprivileged, writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTWN, then CPYMTWN, and then CPYETWN.
CPYPTWN performs some preconditioning of the arguments suitable for using the CPYMTWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMTWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYETWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPTWN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPTWN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPTWN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMTWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMTWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYETWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYETWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

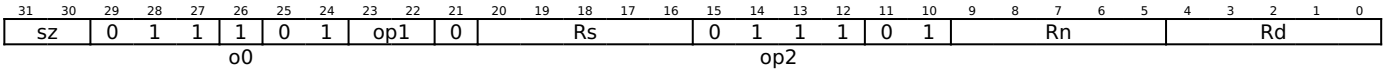
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYETWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *Memory Copy and Memory Set CPY** and *Crossing a page boundary with different memory types or Shareability attributes*.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the "Rn" field.

CPYPWN, CPYMWN, CPYEWN

Memory copy, writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWN, then CPYMWN, and then CPYEWN.
CPYPWN performs some preconditioning of the arguments suitable for using the CPYMWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYEWN, option A, when PSTATE.C = 0:

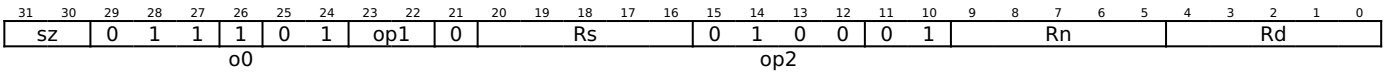
- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYEWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYEWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the "Rn" field.

CPYPWT, CPYMWT, CPYEWT

Memory copy, writes unprivileged

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWT, then CPYMWT, and then CPYEWT.
CPYPWT performs some preconditioning of the arguments suitable for using the CPYMWT instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWT copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWT copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWT:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWT, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWT, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWT, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWT, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYEWT, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYEWT, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYPWTN, CPYMWTN, CPYEWTN

Memory copy, writes unprivileged, reads and writes non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTN, then CPYMWTN, and then CPYEWTN.
CPYPWTN performs some preconditioning of the arguments suitable for using the CPYMWTN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWTN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWTN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWTN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWTN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWTN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWTN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWTN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.

- Xd holds the lowest address to be copied to.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.

- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
  - On completion of the instruction:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address that has not been copied from + 1.
    - Xd holds the highest address that has not been copied to + 1.

For CPYEWTN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

For CPYEWTN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address to be copied from.
  - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address to be copied from + 1.
  - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
  - Xn holds 0.
  - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied from.
    - The highest address that has been copied from + 1.
  - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
    - The lowest address that has been copied to.
    - The highest address that has not been copied to + 1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYPWTRN, CPYMWTRN, CPYEWTRN

Memory copy, writes unprivileged, reads non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTRN, then CPYMWTRN, and then CPYEWTRN.
CPYPWTRN performs some preconditioning of the arguments suitable for using the CPYMWTRN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWTRN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWTRN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWTRN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWTRN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWTRN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWTRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWTRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.

- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address to be copied from.
    - Xd holds the lowest address to be copied to.
    - On completion of the instruction:
        - Xn holds the number of bytes remaining to be copied.
        - Xs holds the lowest address that has not been copied from.
        - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address to be copied from + 1.
    - Xd holds the highest address to be copied to + 1.
    - On completion of the instruction:
        - Xn holds the number of bytes remaining to be copied.
        - Xs holds the highest address that has not been copied from + 1.
        - Xd holds the highest address that has not been copied to + 1.

For CPYEWTRN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

For CPYEWTRN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address to be copied from.
    - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address to be copied from + 1.
    - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

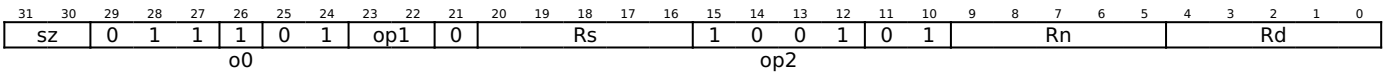
Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPWTRN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMWTRN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYEWTRN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *Memory Copy and Memory Set CPY** and *Crossing a page boundary with different memory types or Shareability attributes*.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the "Rn" field.

CPYPWTWN, CPYMWTWN, CPYEWTWN

Memory copy, writes unprivileged and non-temporal

These instructions copy a requested number of bytes in memory from a source address to a destination address. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTWN, then CPYMWTWN, and then CPYEWTWN.
CPYPWTWN performs some preconditioning of the arguments suitable for using the CPYMWTWN instruction, and copies an IMPLEMENTATION DEFINED portion of the requested number of bytes. CPYMWTWN copies a further IMPLEMENTATION DEFINED portion of the remaining bytes. CPYEWTWN copies any final remaining bytes.

Note

The ability to copy an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being copied are divided between the different instructions.

For more information on exceptions specific to memory copy instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For CPYPWTWN:

- If Xn[63:55] != '000000000', the copy size Xn is saturated to 0x007FFFFFFFFFFF.
- After saturation is performed, the direction of the memory copy is based on the following:
  If (Xs[55:0] > Xd[55:0]) and (Xd[55:0] + saturated copy size) > Xs[55:0], then the direction is forward.
  If (Xs[55:0] < Xd[55:0]) and (Xs[55:0] + saturated copy size) > Xd[55:0], then the direction is backward.
  Otherwise, the direction is an IMPLEMENTATION DEFINED choice between forward and backward.

On completion of CPYPWTWN, option A:

- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.
- If the copy is in the forward direction, then:
  - Xn holds -1 times the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the original Xs + saturated copy size.
  - Xd holds the original Xd + saturated copy size.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs and Xd are unchanged.

On completion of CPYPWTWN, option B:

- If the copy is in the forward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the lowest address that has not been copied from.
  - Xd holds the lowest address that has not been copied to.
  - PSTATE.{N,Z,C,V} are set to {0,0,1,0}.
- If the copy is in the backward direction, then:
  - Xn holds the number of bytes in the saturated copy size remaining to be copied.
  - Xs holds the highest address that has not been copied from + 1.
  - Xd holds the highest address that has not been copied to + 1.
  - PSTATE.{N,Z,C,V} are set to {1,0,1,0}.

For CPYMWTWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
  - Xn holds -1 times the number of bytes remaining to be copied.
  - Xs holds the lowest address to be copied from - Xn.
  - Xd holds the lowest address to be copied to - Xn.
  - On completion of the instruction, Xn holds -1 times the number of bytes remaining to be copied.
- If the copy is in the backward direction (Xn holds a positive number), then:
  - Xn holds the number of bytes remaining to be copied.
  - Xs holds the highest address to be copied from + 1 - Xn.
  - Xd holds the highest address to be copied to + 1 - Xn.
  - On completion of the instruction, Xn holds the number of bytes remaining to be copied.

For CPYMWTWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.

- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address to be copied from.
    - Xd holds the lowest address to be copied to.
    - On completion of the instruction:
        - Xn holds the number of bytes remaining to be copied.
        - Xs holds the lowest address that has not been copied from.
        - Xd holds the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address to be copied from + 1.
    - Xd holds the highest address to be copied to + 1.
    - On completion of the instruction:
        - Xn holds the number of bytes remaining to be copied.
        - Xs holds the highest address that has not been copied from + 1.
        - Xd holds the highest address that has not been copied to + 1.

For CPYEWTWN, option A, when PSTATE.C = 0:

- Xn holds a signed 64-bit integer.
- If the copy is in the forward direction (Xn holds a negative number), then:
    - Xn holds -1 times the number of bytes remaining to be copied.
    - Xs holds the lowest address to be copied from - Xn.
    - Xd holds the lowest address to be copied to - Xn.
- If the copy is in the backward direction (Xn holds a positive number), then:
    - Xn holds the number of bytes remaining to be copied.
    - Xs holds the highest address to be copied from + 1 - Xn.
    - Xd holds the highest address to be copied to + 1 - Xn.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

For CPYEWTWN, option B, when PSTATE.C = 1:

- Xn holds the number of bytes remaining to be copied.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address to be copied from.
    - Xd holds the lowest address to be copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address to be copied from + 1.
    - Xd holds the highest address to be copied to + 1.
- On completion of the instruction:
    - Xn holds 0.
    - Xs holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied from.
        - The highest address that has been copied from + 1.
    - Xd holds an IMPLEMENTATION SPECIFIC value in the range with bounds:
        - The lowest address that has been copied to.
        - The highest address that has not been copied to + 1.

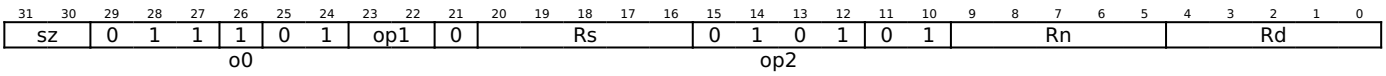
Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op1 == 00)`

```
CPYPWTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Main variant

Applies when `(op1 == 01)`

```
CPYMWTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Encoding for the Epilogue variant

Applies when `(op1 == 10)`

```
CPYEWTWN [<Xd>]!, [<Xs>]!, <Xn>!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memcpy : CPYParams;
memcpy.d = UInt(Rd);
memcpy.s = UInt(Rs);
memcpy.n = UInt(Rn);
let options : bits(4) = op2;
let rnontemporal : boolean = options[3] == '1';
let wnontemporal : boolean = options[2] == '1';
case op1 of
    when '00' => memcpy.stage = MOPSStage_Prologue;
    when '01' => memcpy.stage = MOPSStage_Main;
    when '10' => memcpy.stage = MOPSStage_Epilogue;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *Memory Copy and Memory Set CPY** and *Crossing a page boundary with different memory types or Shareability attributes*.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero on completion of the instruction, encoded in the "Rn" field.

CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum

This instruction performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

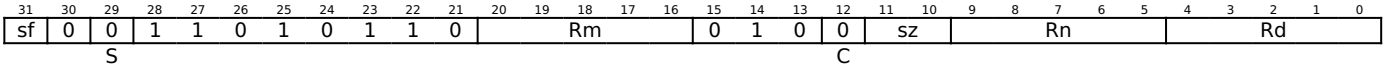
In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

CRC

(FEAT_CRC32)



Encoding for the CRC32B variant

Applies when `(sf == 0 && sz == 00)`

```
CRC32B <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32H variant

Applies when `(sf == 0 && sz == 01)`

```
CRC32H <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32W variant

Applies when `(sf == 0 && sz == 10)`

```
CRC32W <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32X variant

Applies when `(sf == 1 && sz == 11)`

```
CRC32X <Wd>, <Wn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CRC32) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
if sf == '1' && sz != '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && sz == '11' then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = 8 << UInt(sz);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.
<Xm>	Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.

Operation

```
let acc : bits(32) = X{32}(n);       // accumulator
let val : bits(size) = X{size}(m);   // input value
let poly : bits(32) = 0x4C11DB7[:32];

let tempacc : bits(32+size) = BitReverse{32}(acc)::Zeros{size};
let tempval : bits(size+32) = BitReverse{size}(val)::Zeros{32};

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X{32}(d) = BitReverse{32}(Poly32Mod2{32+size}(tempacc XOR tempval, poly));
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32C checksum

This instruction performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

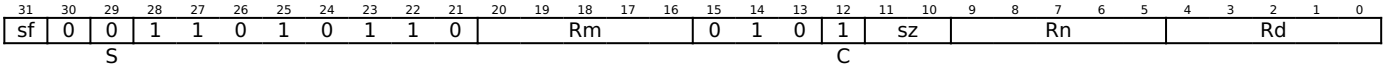
In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

CRC

(FEAT_CRC32)



Encoding for the CRC32CB variant

Applies when `(sf == 0 && sz == 00)`

```
CRC32CB <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CH variant

Applies when `(sf == 0 && sz == 01)`

```
CRC32CH <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CW variant

Applies when `(sf == 0 && sz == 10)`

```
CRC32CW <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CX variant

Applies when `(sf == 1 && sz == 11)`

```
CRC32CX <Wd>, <Wn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CRC32) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
if sf == '1' && sz != '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && sz == '11' then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = 8 << UInt(sz);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.
<Xm>	Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.

Operation

```
let acc : bits(32) = X{32}(n);       // accumulator
let val : bits(size) = X{size}(m);   // input value
let poly : bits(32) = 0x1EDC6F41[:32];

let tempacc : bits(32+size) = BitReverse{32}(acc)::Zeros{size};
let tempval : bits(size+32) = BitReverse{size}(val)::Zeros{32};

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X{32}(d) = BitReverse{32}(Poly32Mod2{32+size}(tempacc XOR tempval, poly));
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

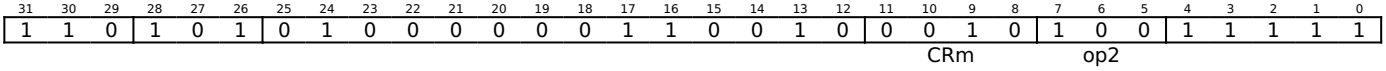
CSDB

Consumption of speculative data barrier

This instruction is a memory barrier that controls speculative execution arising from data value prediction. For more information and details of the semantics, see *Consumption of Speculative Data Barrier (CSDB)*.



Encoding

CSDB

Decode for this encoding

```
// Empty.
```

Operation

```
ConsumptionOfSpeculativeDataBarrier();
```

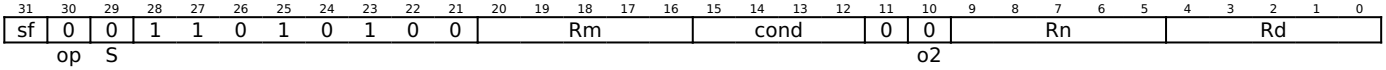
CSEL

Conditional select

This instruction writes the value of the first source register to the destination register if the condition is TRUE. If the condition is FALSE, it writes the value of the second source register to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSEL <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSEL <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
var result : bits(datasize);
if ConditionHolds(condition) then
    result = X{datasize}(n);
else
    result = X{datasize}(m);
end;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

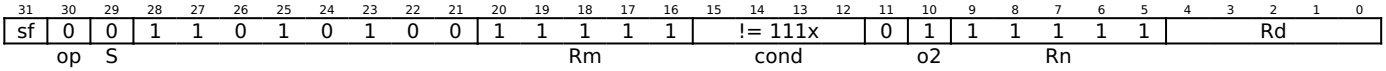
CSET

Conditional set

This instruction sets the destination register to 1 if the condition is TRUE, and otherwise sets it to 0.

This is an alias of CSINC. This means:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSET <Wd>, <invcond>
```

is equivalent to

```
CSINC <Wd>, WZR, WZR, <cond>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSET <Xd>, <invcond>
```

is equivalent to

```
CSINC <Xd>, XZR, XZR, <cond>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<invcond> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in “cond”:

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC|LO	Maps to <cond> CS.
0011	CS|HS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.
0110	VC	Maps to <cond> VS.
0111	VS	Maps to <cond> VC.
1000	LS	Maps to <cond> HI.
1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational Information

The description of CSINC gives the operational information for this instruction.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

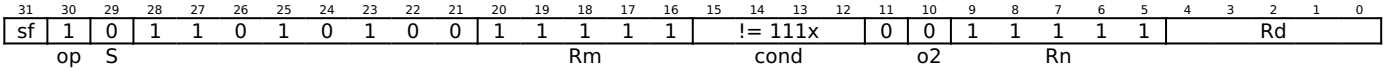
CSETM

Conditional set mask

This instruction sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSETM <Wd>, <invcond>
```

is equivalent to

```
CSINV <Wd>, WZR, WZR, <cond>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSETM <Xd>, <invcond>
```

is equivalent to

```
CSINV <Xd>, XZR, XZR, <cond>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<invcond> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in “cond”:

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC|LO	Maps to <cond> CS.
0011	CS|HS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.
0110	VC	Maps to <cond> VS.
0111	VS	Maps to <cond> VC.
1000	LS	Maps to <cond> HI.
1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

Operational Information

The description of CSINV gives the operational information for this instruction.

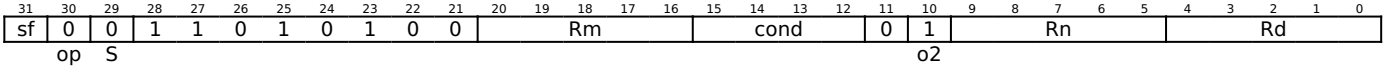
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

CSINC

Conditional select increment

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases CINC, and CSET.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSINC <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSINC <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CINC	`Rm != '11111' && Rn != '11111' && !(cond IN {'111x'}) && Rn == Rm`
CSET	`Rm == '11111' && Rn == '11111' && !(cond IN {'111x'})`

Operation

```
var result : bits(datasize);
if ConditionHolds(condition) then
    result = X{datasize}(n);
else
    result = X{datasize}(m) + 1;
end;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

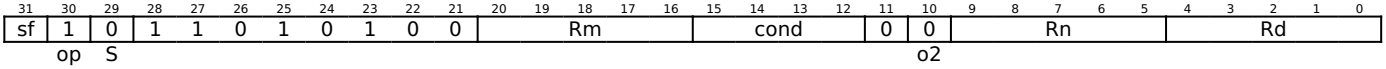
CSINV

Conditional select invert

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases CINV, and CSETM.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSINV <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSINV <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CINV	`Rm != '11111' && Rn != '11111' && !(cond IN {'111x'}) && Rn == Rm`
CSETM	`Rm == '11111' && Rn == '11111' && !(cond IN {'111x'})`

Operation

```
var result : bits(datasize);
if ConditionHolds(condition) then
    result = X{datasize}(n);
else
    result = NOT X{datasize}(m);
end;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

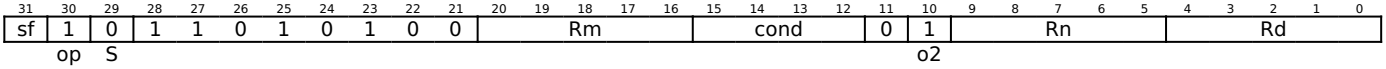
CSNEG

Conditional select negation

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the negated value of the second source register.

This instruction is used by the alias CNEG.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CSNEG <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CSNEG <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let condition : bits(4) = cond;
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CNEG	`!(cond IN {'111x'}) && Rn == Rm`

Operation

```
var result : bits(datasize);
if ConditionHolds(condition) then
    result = X{datasize}(n);
else
    result = NOT X{datasize}(m) + 1;
end;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

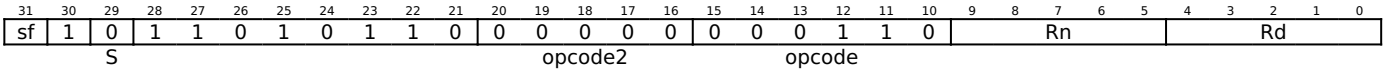
CTZ

Count trailing zeros

This instruction determines the number of consecutive binary zero bits, starting from the least significant bit in the source register, and places the result in the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
CTZ <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
CTZ <Xd>, <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let datasize : integer{} = 32 << UInt(sf);
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = CountLeadingZeroBits(BitReverse{datasize}(operand1));

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

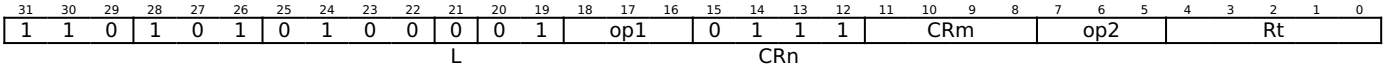
DC

Data cache operation

For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions*.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
DC <dc_op>, <Xt>
```

is equivalent to

```
SYS #<op1>, C7, <Cm>, #<op2>, <Xt>
```

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_DC`.

Assembler Symbols

<dc_op> Is a DC operation name, as listed for the DC system instruction group, encoded in “(op1 :: CRm :: op2)”:

op1	CRm	op2	<dc_op>	Architectural Feature	Description
000	0110	001	IVAC	-	For more information, see DC IVAC.
000	0110	010	ISW	-	For more information, see DC ISW.

DCPS1

Debug change PE state to EL1

This instruction, when executed in Debug state:

- If executed at EL0, changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects *SP_ELx*.

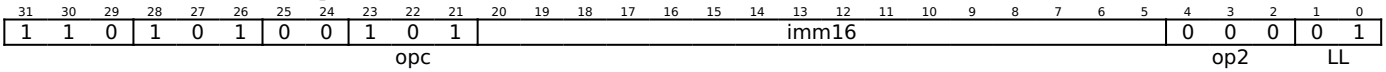
The target Exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- *ELR_ELx* becomes UNKNOWN.
- *SPSR_ELx* becomes UNKNOWN.
- *ESR_ELx* becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to *SCTLR_ELx*.EE.

This instruction is always UNDEFINED in Non-debug state.
This instruction is UNDEFINED at EL0 if EL2 is implemented and enabled in the current Security state and *HCR_EL2*.TGE == 1.
For more information on the operation of the DCPS<n> instructions, see *DCPS*.



Encoding

```
DCPS1 {#<imm>}
```

Decode for this encoding

```
// Empty.
```

Assembler Symbols

<imm>	Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
if !Halted() then Undefined(); end;
DCPSInstruction(EL1);
```

2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

DCPS2

Debug change PE state to EL2

This instruction, when executed in Debug state:

- If executed at EL0 or EL1, changes the current Exception level and SP to EL2 using SP_EL2.
- Otherwise, if executed at ELx, selects *SP_ELx*.

The target Exception level of a DCPS2 instruction is:

- EL2 if the instruction is executed at an Exception level that is not EL3.
- EL3 if the instruction is executed at EL3.

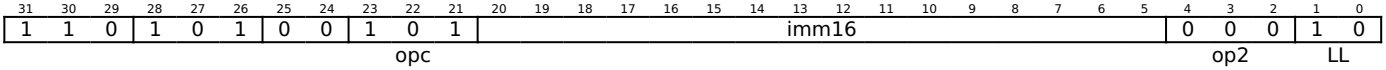
When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

- *ELR_ELx* becomes UNKNOWN.
- *SPSR_ELx* becomes UNKNOWN.
- *ESR_ELx* becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to *SCTLR_ELx*.EE.

This instruction is always UNDEFINED in Non-debug state.
This instruction is UNDEFINED at the following Exception levels:

- All Exception levels if EL2 is not implemented.
- At EL0 and EL1 if EL2 is disabled in the current Security state.

For more information on the operation of the DCPS<n> instructions, see *DCPS*.



Encoding

```
DCPS2 {#<imm>}
```

Decode for this encoding

```
// Empty.
```

Assembler Symbols

<imm>	Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
if !Halted() then Undefined(); end;
DCPSInstruction(EL2);
```

DCPS3

Debug change PE state to EL3

This instruction, when executed in Debug state:

- If executed at EL3, selects SP_EL3.
- Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

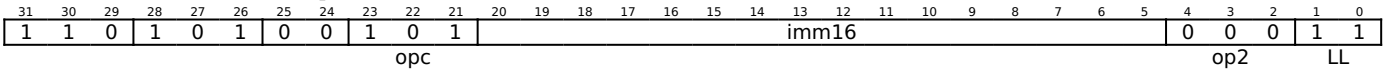
The target Exception level of a DCPS3 instruction is EL3.
On executing a DCPS3 instruction:

- ELR_EL3 becomes UNKNOWN.
- SPSR_EL3 becomes UNKNOWN.
- ESR_EL3 becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_EL3.EE.

This instruction is always UNDEFINED in Non-debug state.
This instruction is UNDEFINED at all Exception levels if either:

- *EDSCR*.SDD == 1.
- EL3 is not implemented.

For more information on the operation of the DCPS<n> instructions, see *DCPS*.



Encoding

```
DCPS3 {#<imm>}
```

Decode for this encoding

```
// Empty.
```

Assembler Symbols

<imm>	Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
if !Halted() then Undefined(); end;
DCPSInstruction(EL3);
```

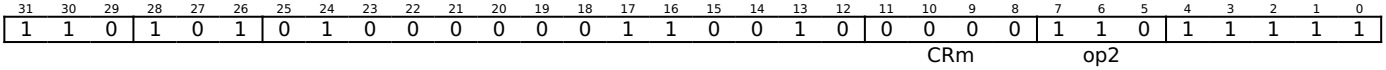
DGH

Data gathering hint

This instruction is a hint instruction that indicates that it is not expected to be performance optimal to merge memory accesses with Normal Non-cacheable or Device-GRE attributes appearing in program order before the hint instruction with any memory accesses appearing after the hint instruction into a single memory transaction on an interconnect.

System

(FEAT_DGH)



Encoding

DGH

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_DGH) then EndOfDecode(Decode_NOP); end;
```

Operation

```
Hint_DGH();
```

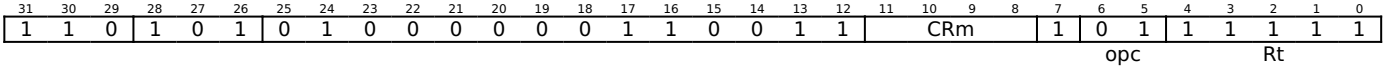
DMB

Data memory barrier

This instruction is a memory barrier that ensures the ordering of observations of memory accesses, see *Data Memory Barrier*.



Encoding

```
DMB  (<option>|#<imm>)
```

Decode for this encoding

```
var types : MBReqTypes;
case CRm[1:0] of
    when '00' => types = MBReqTypes_All;
    when '01' => types = MBReqTypes_Reads;
    when '10' => types = MBReqTypes_Writes;
    when '11' => types = MBReqTypes_All;
end;
```

Assembler Symbols

<option> Specifies the limitation on the Memory Effects ordered by the barrier operation, and is encoded in "CRm". For more information on whether a Memory Effect is before or after a barrier instruction, see *Data Memory Barrier (DMB)*.

CRm	<option>	Description
xx00	RESERVED	
0001	OSHLD	This option has the same behavior as LD and is deprecated.
0010	OSHST	This option has the same behavior as ST and is deprecated.
0011	OSH	This option has the same behavior as SY and is deprecated.
0101	NSHLD	This option has the same behavior as LD and is deprecated.
0110	NSHST	This option has the same behavior as ST and is deprecated.
0111	NSH	This option has the same behavior as SY and is deprecated.
1001	ISHLD	This option has the same behavior as LD and is deprecated.
1010	ISHST	This option has the same behavior as ST and is deprecated.
1011	ISH	This option has the same behavior as SY and is deprecated.
1101	LD	Reads are the required access type before the barrier instruction. Reads and writes are the required access types after the barrier instruction.
1110	ST	Writes are the required access type, both before and after the barrier instruction.
1111	SY	Reads and writes are the required access types, both before and after the barrier instruction.

All encodings of "CRm" that are listed as reserved can be encoded using the #<imm> syntax. All reserved options have the same behavior as SY, but software must not rely on this behavior.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

```
DataMemoryBarrier(types);
```

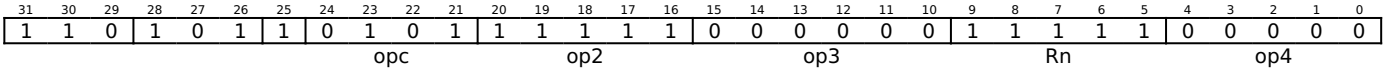
DRPS

Debug restore PE state

This instruction restores *PSTATE* from the SPSR.
The SPSR is checked for the current Exception level for an illegal return event. See *Illegal exception returns from AArch64 state*.
This instruction is UNDEFINED in Non-debug state.
This instruction is UNDEFINED at EL0.
For more information on the operation of DRPS, see *DRPS*.



Encoding

DRPS

Decode for this encoding

```
// Empty.
```

Operation

```
if !Halted() || PSTATE.EL == EL0 then Undefined(); end;
DRPSInstruction();
```

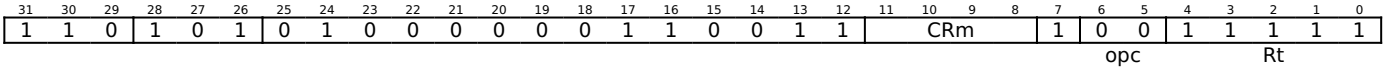
DSB

Data synchronization barrier

This instruction is a memory barrier that ensures the completion of memory accesses, see *Data Synchronization Barrier*.
This instruction is used by the aliases PSSBB, and SSBB.
It has encodings from 2 classes: Memory barrier and Memory nXS barrier

Memory barrier



Encoding

```
DSB (<option>|#<imm>)
```

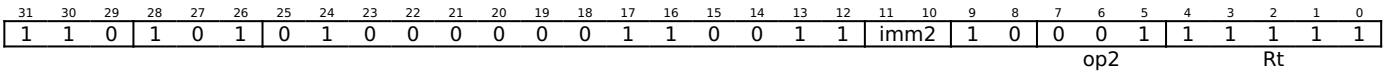
Decode for this encoding

```
var types : MBReqTypes;
var nXS : boolean = FALSE;
var alias : DSBAlias;
var scope : MBMaintenanceScope;
case CRm of
    when '0000' => alias = DSBAlias_SSBB;
    when '0100' => alias = DSBAlias_PSSBB;
    otherwise   => alias = DSBAlias_DSB;
end;

case CRm[1:0] of
    when '00' =>
        types = MBReqTypes_All;
        scope = MBMaintenanceScope_OuterShareable;
    when '01' =>
        types = MBReqTypes_Reads;
        scope = MBMaintenanceScope_None;
    when '10' =>
        types = MBReqTypes_Writes;
        scope = MBMaintenanceScope_None;
    when '11' =>
        types = MBReqTypes_All;
        case CRm[3:2] of
            when '00' => scope = MBMaintenanceScope_OuterShareable;
            when '01' => scope = MBMaintenanceScope_Nonshareable;
            when '10' => scope = MBMaintenanceScope_InnerShareable;
            when '11' => scope = MBMaintenanceScope_OuterShareable;
        end;
end;
```

Memory nXS barrier

(FEAT_XS)



Encoding

```
DSB <option>nXS
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_XS) then EndOfDecode(Decode_UNDEF); end;
let types : MBReqTypes = MBReqTypes_All;
var nXS : boolean = TRUE;
let alias : DSBAlias = DSBAlias_DSB;
var scope : MBMaintenanceScope;
case imm2 of
    when '00' => scope = MBMaintenanceScope_OuterShareable;
    when '01' => scope = MBMaintenanceScope_Nonshareable;
    when '10' => scope = MBMaintenanceScope_InnerShareable;
    when '11' => scope = MBMaintenanceScope_OuterShareable;
end;
```

Assembler Symbols

<option> For the "Memory barrier" variant: specifies the limitation on the Memory Effects and maintenance operations ordered by the barrier operation, and is encoded in "CRm".

Note

The value 0b0000 is used to encode `SSBB` and the value 0b0100 is used to encode `PSSBB`.

For more information on whether an access is before or after a barrier instruction, see *Data Synchronization Barrier (DSB)*.

CRm	<option>	Description
0001	OSHLD	This option has the same behavior as LD and is deprecated.
0010	OSHST	This option has the same behavior as ST and is deprecated.
0011	OSH	This option has the same behavior as SY.
0101	NSHLD	This option has the same behavior as LD and is deprecated.
0110	NSHST	This option has the same behavior as ST and is deprecated.
0111	NSH	Non-shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.
1x00	RESERVED	
1001	ISHLD	This option has the same behavior as LD and is deprecated.
1010	ISHST	This option has the same behavior as ST and is deprecated.
1011	ISH	Inner Shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.
1101	LD	Reads are the required access type before the barrier instruction. Reads and writes are the required access types after the barrier instruction.
1110	ST	Writes are the required access type, both before and after the barrier instruction.
1111	SY	Outer Shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.

All encodings of "CRm" that are listed as reserved can be encoded using the #<imm> syntax. All reserved options have the same behavior as SY, but software must not rely on this behavior.

For the "Memory nXS barrier" variant: specifies the limitation on the barrier operation, and is encoded in “imm2”:

imm2	<option>	Description
00	OSH	This option has the same behavior as SY.
01	NSH	Non-shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.
10	ISH	Inner Shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.
11	SY	Outer Shareable is the required maintenance scope. Reads and writes are the required access types, both before and after the barrier instruction.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Alias Conditions

Alias	Is preferred when
PSSBB	`CRm == '0100'`
SSBB	`CRm == '0000'`

Operation

```
case alias of
    when DSBAlias_SSBB =>
        SpeculativeStoreBypassBarrierToVA();
    when DSBAlias_PSSBB =>
        SpeculativeStoreBypassBarrierToPA();
    when DSBAlias_DSB =>
        if !nXS && IsFeatureImplemented(FEAT_XS) then
            nXS = PSTATE.EL IN {EL0, EL1} && IsHCRXEL2Enabled() && HCRX_EL2().FnXS == '1';
        end;
        DataSynchronizationBarrier(scope, types, nXS);
    otherwise =>
        unreachable;
end;
```

DVP

Data value prediction restriction by context

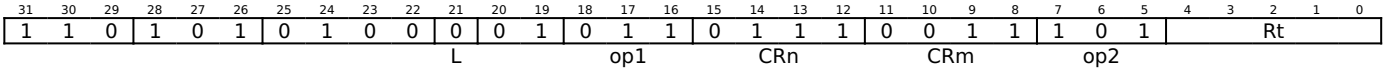
This instruction prevents data value predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.
For more information, see DVP RCTX, Data Value Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SPECRES)



Encoding

```
DVP RCTX, <Xt>
```

is equivalent to

```
SYS #3, C7, C3, #5, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

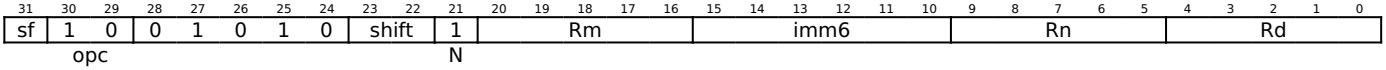
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

EON (shifted register)

Bitwise exclusive-OR NOT (shifted register)

This instruction performs a bitwise exclusive-OR NOT between a register value and an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
EON <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
EON <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 XOR NOT operand2;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

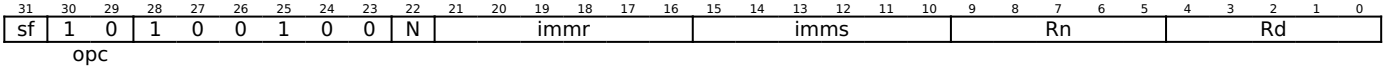
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

EOR (immediate)

Bitwise exclusive-OR (immediate)

This instruction performs a bitwise exclusive-OR between a register value and an immediate value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
EOR <Wd|WSP>, <Wn>, #<imm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
EOR <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
var imm : bits(datasize);
(imm, -) = DecodeBitMasks{datasize}(N, imms, immr, TRUE);
```

Assembler Symbols

<Wd|WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	Is the bitmask immediate. For encoding information, see *Logical (immediate)*.
<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = imm;
let result : bits(datasize) = operand1 XOR operand2;

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

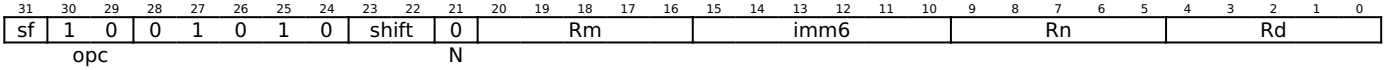
EOR (shifted register)

Bitwise exclusive-OR (shifted register)

This instruction performs a bitwise exclusive-OR between a register value and an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
EOR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
EOR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 XOR operand2;

X{datasize}(d) = result;
```

Operational information

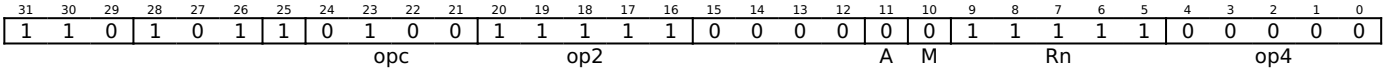
ERET

Exception return

This instruction restores *PSTATE* from the SPSR, and branches to the address held in the ELR.
The SPSR is checked for the current Exception level for an illegal return event. See *Illegal exception returns from AArch64 state*.
ERET is UNDEFINED at EL0.



Encoding

ERET

Decode for this encoding

```
let pac : boolean = FALSE;
let use_key_a : boolean = TRUE;
```

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;
AArch64_CheckForERetTrap(pac, use_key_a);
let target : bits(64) = ELR_ELx();

AArch64_ExceptionReturn(target, SPSR_ELx());
```

ERETAA, ERETAB

Exception return, with pointer authentication

This instruction authenticates the address in ELR, using SP as the modifier and the specified key, restores *PSTATE* from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for ERETAA. Key B is used for ERETAB.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

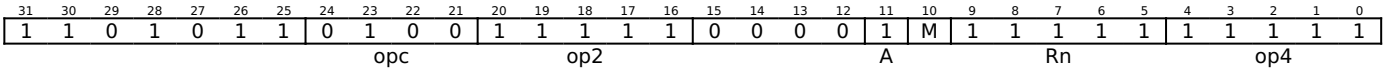
The authenticated address is not written back to ELR.

The SPSR is checked for the current Exception level for an illegal return event. See *Illegal exception returns from AArch64 state*.

ERETAA and ERETAB are UNDEFINED at EL0.

Integer

(FEAT_PAuth)



Encoding for the ERETAA variant

Applies when (M == 0)

ERETAA

Encoding for the ERETAB variant

Applies when (M == 1)

ERETAB

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let use_key_a : boolean = (M == '0');
let pac : boolean = TRUE;
let auth_then_branch : boolean = TRUE;
```

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;
AArch64_CheckForERetTrap(pac, use_key_a);

var target : bits(64) = ELR_ELx();
let modifier : bits(64) = SP{64}();
if use_key_a then
    target = AuthIA(target, modifier, auth_then_branch);
else
    target = AuthIB(target, modifier, auth_then_branch);
end;

AArch64_ExceptionReturn(target, SPSR_ELx());
```

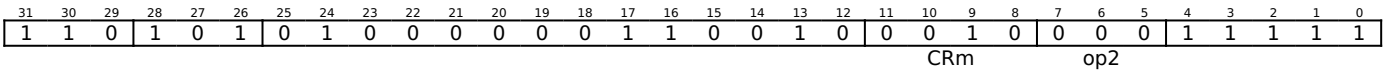
ESB

Error synchronization barrier

This instruction is an error synchronization event that might also update DISR_EL1 and VDISR_EL2.
This instruction can be used at all Exception levels and in Debug state.
In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. For more information, see *RAS PE architecture* and Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture (ARM IHI 0100).
If *FEAT_RAS* is not implemented, this instruction executes as a `NOP`.

System

(FEAT_RAS)



Encoding

```
ESB
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_RAS) then EndOfDecode(Decode_NOP); end;
```

Operation

```
SynchronizeErrors();
AArch64_ESBOperation();
if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
    AArch64_vESBOperation();
elsif IsFeatureImplemented(FEAT_E3DSE) && PSTATE.EL != EL3 then
    AArch64_dESBOperation();
end;
TakeUnmaskedSErrorInterrupts();
```

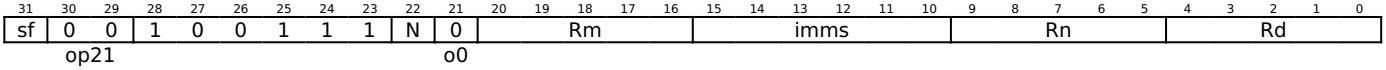
EXTR

Extract register

This instruction extracts a register from a pair of registers.
This instruction is used by the alias ROR (immediate).



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms == 0xxxxx)`

```
EXTR <Wd>, <Wn>, <Wm>, #<lsb>
```

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
EXTR <Xd>, <Xn>, <Xm>, #<lsb>
```

Decode for all variants of this encoding

```
if N != sf then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && imms[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let lsb : integer{} = UInt(imms);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<lsb>	For the "32-bit" variant: is the least significant bit position from which to extract, in the range 0 to 31, encoded in the "imms" field. For the "64-bit" variant: is the least significant bit position from which to extract, in the range 0 to 63, encoded in the "imms" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
ROR (immediate)	`Rn == Rm`

Operation

```
var result : bits(datasize);
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let concat : bits(2*datasize) = operand1::operand2;

result = concat[(lsb+datasize)-1:lsb];

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

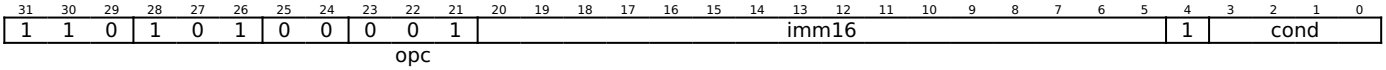
FLT.cond

Conditional fault

This instruction conditionally generates a Conditional fault exception. If an exception is generated, the immediate field is copied to ESR_ELx.

System

(FEAT_CFLT)



Encoding

```
FLT.<cond> #<imm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CFLT) then EndOfDecode(Decode_UNDEF); end;
let imm : bits(16) = imm16;
let condition : bits(4) = cond;
```

Assembler Symbols

<cond> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS|HS
0011	CC|LO
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
CheckCFLTEnabled();

if ConditionHolds(condition) then
    let isflt : boolean = TRUE;
    AArch64_ConditionalFault(isflt, imm);
end;
```

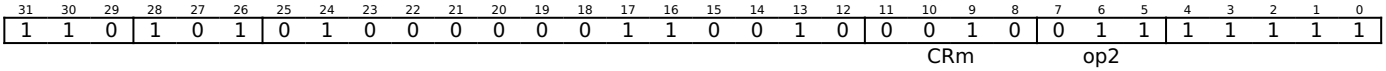
GCSB

Guarded Control Stack barrier

This instruction generates a GCSB effect.
If *FEAT_GCS* is not implemented, this instruction executes as a `NOP`.

System

(FEAT_GCS)



Encoding

```
GCSB DSYNC
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_GCS) then EndOfDecode(Decode_NOP); end;
```

Operation

```
GCSSynchronizationBarrier();
```

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

GCSPOPCX

Guarded Control Stack pop and compare exception return record

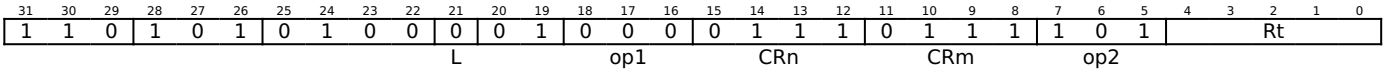
This instruction loads an exception return record from the location indicated by the current GCS pointer register, compares the loaded values with the current ELR_ELx, SPSR_ELx, and LR, and increments the pointer by the size of a GCS exception return record.
For more information, see GCSPOPCX, Guarded Control Stack Pop and Compare exception return record.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)



Encoding

```
GCSPOPCX
```

is equivalent to

```
SYS #0, C7, C7, #5{, <Xt>}
```

and is always the preferred disassembly.

Operation

The description of SYS gives the operational pseudocode for this instruction.

2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

GCSPOPM

Guarded Control Stack pop

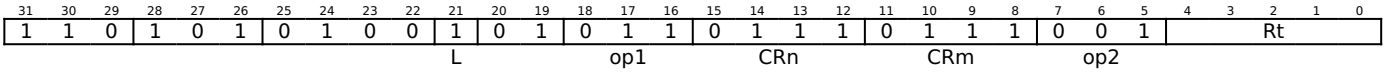
This instruction loads the 64-bit doubleword that is pointed to by the current GCS pointer register, writes it to the destination register, and increments the current GCS pointer register by the size of a GCS procedure return record.
For more information, see GCSPOPM, Guarded Control Stack Pop.

This is an alias of SYSL. This means:

- The encodings in this description are named to match the encodings of SYSL.
- The description of SYSL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)



Encoding

```
GCSPOPM {<Xt>}
```

is equivalent to

```
SYSL <Xt>, #3, C7, C7, #1
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the optional general-purpose destination register, encoded in the "Rt" field. Defaults to XZR if absent.

Operation

The description of SYSL gives the operational pseudocode for this instruction.

GCSPOPX

Guarded Control Stack pop exception return record

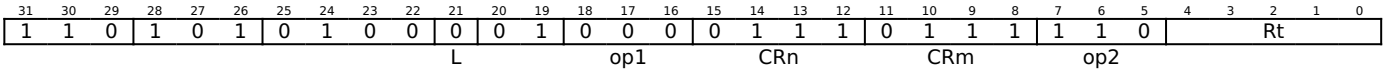
This instruction loads an exception return record from the location indicated by the current GCS pointer register, checks that the record is an exception return record, and increments the pointer by the size of a Guarded Control Stack exception return record.
For more information, see GCSPOPX, Guarded Control Stack Pop exception return record.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)



Encoding

GCSPOPX

is equivalent to

SYS #0, C7, C7, #6{, <Xt>}

and is always the preferred disassembly.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

GCSPUSHM

Guarded Control Stack push

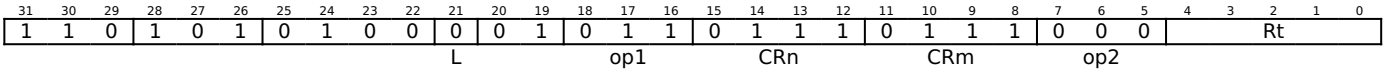
This instruction decrements the current GCS pointer register by the size of a GCS procedure return record and stores an entry to the Guarded Control Stack.
For more information, see GCSPUSHM, Guarded Control Stack Push.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)



Encoding

```
GCSPUSHM <Xt>
```

is equivalent to

```
SYS #3, C7, C7, #0, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

GCSPUSHX

Guarded Control Stack push exception return record

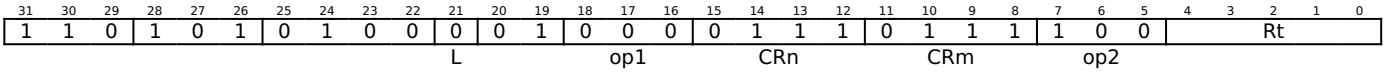
This instruction decrements the current GCS pointer register by the size of a Guarded Control Stack exception return record and stores an exception return record to the Guarded Control Stack.
For more information, see GCSPUSHX, Guarded Control Stack Push exception return record.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)



Encoding

GCSPUSHX

is equivalent to

SYS #0, C7, C7, #4{, <Xt>}

and is always the preferred disassembly.

Operation

The description of SYS gives the operational pseudocode for this instruction.

GCSSS1

Guarded Control Stack switch stack 1

This instruction validates that the stack being switched to contains a Valid GCS cap record, stores an In-progress GCS cap record to the stack that is being switched to, and sets the current GCS pointer register to the stack that is being switched to.

If the instruction generates a synchronous Data Abort exception, Watchpoint exception, GPC exception, or GCS Data Check exception, the value of *GCSPR_ELx* for the current Exception level is restored to the value held in the register before the instruction was executed.

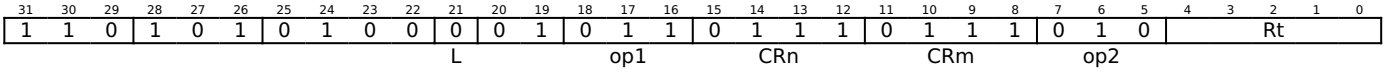
For more information, see GCSSS1, Guarded Control Stack Switch Stack 1.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)



Encoding

```
GCSSS1 <Xt>
```

is equivalent to

```
SYS #3, C7, C7, #2, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

GCSSS2

Guarded Control Stack switch stack 2

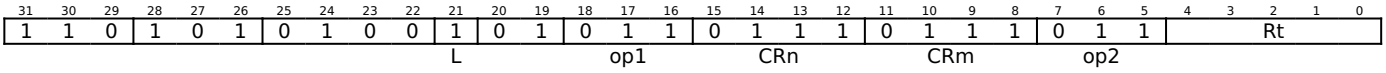
This instruction validates that the most recent entry of the Guarded Control Stack being switched to contains an In-progress GCS cap record, stores a Valid GCS cap record to the Guarded Control Stack that is being switched from, and sets Xt to the Guarded Control Stack pointer that is being switched from.
For more information, see GCSSS2, Guarded Control Stack Switch Stack 2.

This is an alias of SYSL. This means:

- The encodings in this description are named to match the encodings of SYSL.
- The description of SYSL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)



Encoding

```
GCSSS2 <Xt>
```

is equivalent to

```
SYSL <Xt>, #3, C7, C7, #3
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

Operation

The description of SYSL gives the operational pseudocode for this instruction.

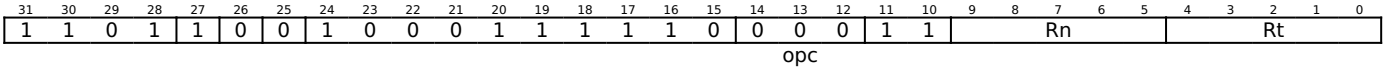
GCSSTR

Guarded Control Stack store register

This instruction stores a doubleword from a register to memory. The address that is used for the store is calculated from a base register.

Integer

(FEAT_GCS)



Encoding

```
GCSSTR <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_GCS) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);

let effective_el : bits(2) = PSTATE.EL;

if effective_el == PSTATE.EL then
    CheckGCSSTREnabled();
end;

let privileged : boolean = effective_el != EL0;
let accdesc : AccessDescriptor = CreateAccDescGCS(MemOp_STORE, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

Mem{64}(address, accdesc) = X{64}(t);
```

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

GCSSTTR

Guarded Control Stack store register (unprivileged)

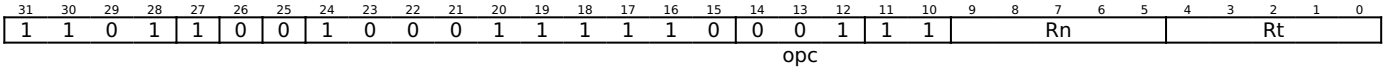
This instruction stores a doubleword from a register to memory. The address that is used for the store is calculated from a base register.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1 and the *Effective value* of *HCR_EL2*.{NV1, NV} is not {1, 1}.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_GCS)



Encoding

```
GCSSTTR <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_GCS) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);

let effective_el : bits(2) = if AArch64_IsUnprivAccessPriv() then PSTATE.EL else EL0;

if effective_el == PSTATE.EL then
    CheckGCSSTREnabled();
end;

let privileged : boolean = effective_el != EL0;
let accdesc : AccessDescriptor = CreateAccDescGCS(MemOp_STORE, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

Mem{64}(address, accdesc) = X{64}(t);
```

GIC

Generic Interrupt Controller

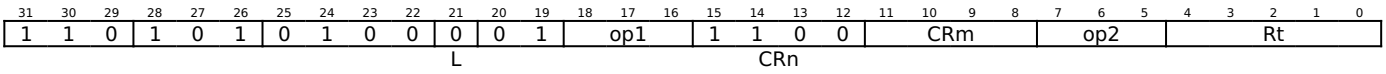
This instruction manages interrupts when FEAT_GCIE is implemented.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCIE)



Encoding

Applies when `(CRm IN {0001, 0010})`

```
GIC <gic_op>{, <Xt>}
```

is equivalent to

```
SYS #<op1>, C12, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1, '1100', CRm, op2) == Sys_GIC`.

Assembler Symbols

<gic_op> Is a GIC operation name, as listed for the GIC system instruction group, encoded in "(op1 :: CRm :: op2)":

op1	CRm	op2	<gic_op>	Description
000	0001	000	CDDIS	For more information, see GIC CDDIS.
000	0001	001	CDEN	For more information, see GIC CDEN.
000	0001	010	CDPRI	For more information, see GIC CDPRI.
000	0001	011	CDAFF	For more information, see GIC CDAFF.
000	0001	100	CDPEND	For more information, see GIC CDPEND.
000	0001	101	CDRCFG	For more information, see GIC CDRCFG.
000	0001	111	CDEOI	For more information, see GIC CDEOI.
000	0010	000	CDDI	For more information, see GIC CDDI.
000	0010	001	CDHM	For more information, see GIC CDHM.
100	0001	000	VDDIS	For more information, see GIC VDDIS.
100	0001	001	VDEN	For more information, see GIC VDEN.
100	0001	010	VDPRI	For more information, see GIC VDPRI.
100	0001	011	VDAFF	For more information, see GIC VDAFF.
100	0001	100	VDPEND	For more information, see GIC VDPEND.
100	0001	101	VDRCFG	For more information, see GIC VDRCFG.
100	0010	000	VDDI	For more information, see GIC VDDI.
100	0010	001	VDHM	For more information, see GIC VDHM.
110	0001	000	LDDIS	For more information, see GIC LDDIS.
110	0001	001	LDEN	For more information, see GIC LDEN.
110	0001	010	LDPRI	For more information, see GIC LDPRI.
110	0001	011	LDAFF	For more information, see GIC LDAFF.
110	0001	100	LDPEND	For more information, see GIC LDPEND.
110	0001	101	LDRCFG	For more information, see GIC LDRCFG.
110	0010	000	LDDI	For more information, see GIC LDDI.
110	0010	001	LDHM	For more information, see GIC LDHM.

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

GICR

Generic Interrupt Controller with result

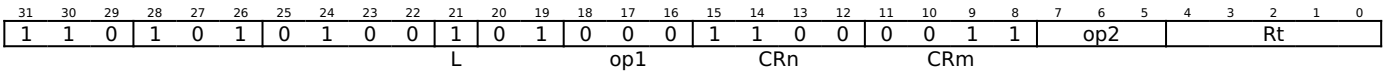
This instruction acknowledges interrupts when FEAT_GCIE is implemented.

This is an alias of SYSL. This means:

- The encodings in this description are named to match the encodings of SYSL.
- The description of SYSL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCIE)



Encoding

```
GICR <Xt>, <gicr_op>
```

is equivalent to

```
SYSL <Xt>, #0, C12, C3, #<op2>
```

and is the preferred disassembly when `SysLOp('000', '1100', '0011', op2) == Sysl_GICR`.

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

<gicr_op> Is a GICR operation name, as listed for the GICR system instruction group, encoded in “op2”:

op2	<gicr_op>	Description
000	CDIA	For more information, see GICR CDIA.
001	CDNMIA	For more information, see GICR CDNMIA.

Operation

The description of SYSL gives the operational pseudocode for this instruction.

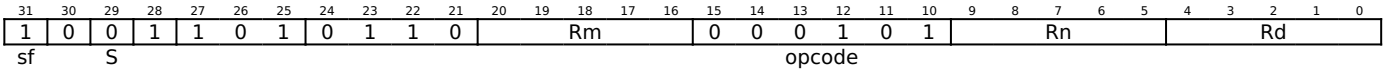
GMI

Tag mask insert

This instruction inserts the tag in the first source register into the excluded set specified in the second source register, writing the new excluded set to the destination register.

Integer

(FEAT_MTE)



Encoding

```
GMI <Xd>, <Xn|SP>, <Xm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let address : bits(64) = if n == 31 then SP{64}() else X{64}(n);
var mask : bits(64) = X{64}(m);
let tag : bits(4) = AArch64_AllocationTagFromAddress(address);

mask[UInt(tag)] = '1';
X{64}(d) = mask;
```

GSB

Generic Interrupt Controller synchronization barrier

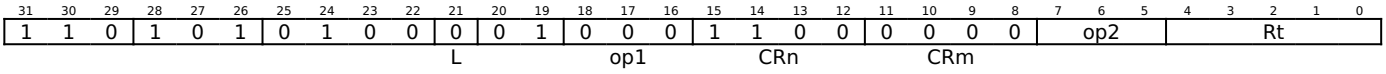
This instruction provides explicit synchronization mechanisms for GIC and GICR System instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCIE)



Encoding

```
GSB <gsb_op>
```

is equivalent to

```
SYS #0, C12, C0, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp('000', '1100', '0000', op2) == Sys_GSB`.

Assembler Symbols

<gsb_op> Is a GSB operation name, as listed for the GSB system instruction group, encoded in “op2”:

op2	<gsb_op>	Description
000	SYS	For more information, see GSB SYS.
001	ACK	For more information, see GSB ACK.

Operation

The description of SYS gives the operational pseudocode for this instruction.

HINT

Hint instruction

This instruction is for the instruction set space that is reserved for architectural hint instructions.

Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

Encoding

```
HINT #<imm>
```

Decode for this encoding

```
var op : SystemHintOp;

var stream : boolean;
var priority : boolean;
var stshstrm : boolean;
case CRm::op2 of

end;
```

Assembler Symbols

<imm> Is a 7-bit unsigned immediate, in the range 0 to 127, encoded in the "CRm:op2" field. The encodings that are allocated to architectural hint functionality are described in the 'Hints' table in the 'Index by Encoding'.

Note

For allocated encodings of "CRm:op2":

- A disassembler will disassemble the allocated instruction, rather than the `HINT` instruction.
- An assembler may support assembly of allocated encodings using `HINT` with the corresponding <imm> value, but it is not required to do so.

Operation

```
case op of
    when SystemHintOp_YIELD =>
        Hint_Yield();

    when SystemHintOp_DGH =>
        Hint_DGH();

    when SystemHintOp_WFE =>
        Hint_WFE();

    when SystemHintOp_WFI =>
        Hint_WFI();

    when SystemHintOp_SEV =>
        SendEvent();

    when SystemHintOp_SEVL =>
        SendEventLocal();

    when SystemHintOp_ESB =>
        SynchronizeErrors();
        AArch64_ESBOperation();
        if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
            AArch64_vESBOperation();
        elsif IsFeatureImplemented(FEAT_E3DSE) && PSTATE.EL != EL3 then
            AArch64_dESBOperation();
        end;
        TakeUnmaskedSErrorInterrupts();

    when SystemHintOp_PSB =>

HINTE

Hint instruction (extended)

This instruction is the extended instruction set space that is reserved for future architectural hint instructions. The encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

System

(FEAT_HINTE)

Encoding

Applies when `(!(L == 0 && imm3 == 011 && Rt == 11111))`

```
HINTE #<imm16>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_HINTE) then EndOfDecode(Decode_UNDEF); end;
```

Assembler Symbols

<imm16>	Is a 16-bit unsigned immediate, in the range 0 to 65535, excluding the values 12319 to 16383 in increments of 32, encoded in the "L:imm3:imm7:Rt" fields.

Operation

```
return; // Do nothing
```

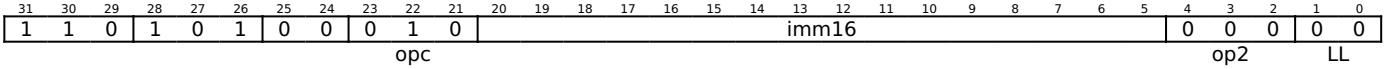
2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

HLT

Halt instruction

This instruction can generate a Halt Instruction debug event, which causes entry into Debug state.
Within a guarded memory region, while *PSTATE*.BTYPE != 0b00, an `HLT` instruction that would cause entry into Debug state will not generate a Branch Target exception and will cause entry into Debug state as normal. For more information, see *PSTATE.BTYPE*.



Encoding

```
HLT #<imm>
```

Decode for this encoding

```
if EDSCR().HDE == '0' || !HaltingAllowed() then
    EndOfDecode(Decode_UNDEF);
elsif IsFeatureImplemented(FEAT_BTI) then
    SetBTypeCompatible(TRUE);
end;
```

Assembler Symbols

<imm>	Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
let is_async : boolean = FALSE;
let fault : FaultRecord = NoFault();
Halt(DebugHalt_HaltInstruction, is_async, fault);
```

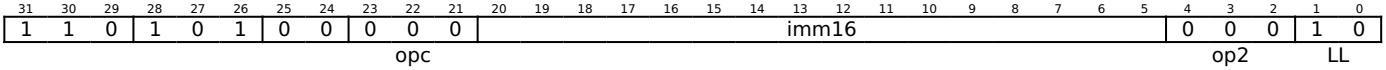
HVC

Hypervisor call

This instruction causes an exception to EL2. Software executing at EL1 can use this instruction to call the hypervisor to request a service.
The HVC instruction is UNDEFINED:

- When EL3 is implemented and SCR_EL3.HCE is set to 0.
- When EL3 is not implemented and *HCR_EL2*.HCD is set to 1.
- When EL2 is not implemented.
- At EL1 if EL2 is not enabled in the current Security state.
- At EL0.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception in *ESR_ELx*, using the EC syndrome value 0x16, and the value of the immediate argument.



Encoding

```
HVC #<imm>
```

Decode for this encoding

```
if !HaveEL(EL2) then EndOfDecode(Decode_UNDEF); end;
let imm : bits(16) = imm16;
```

Assembler Symbols

<imm>	Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;
if PSTATE.EL == EL1 && !EL2Enabled() then Undefined(); end;
if !HaveEL(EL3) && HCR_EL2().HCD == '1' then Undefined(); end;
if HaveEL(EL3) && SCR_EL3().HCE == '0' then Undefined(); end;

AArch64_CallHypervisor(imm);
```

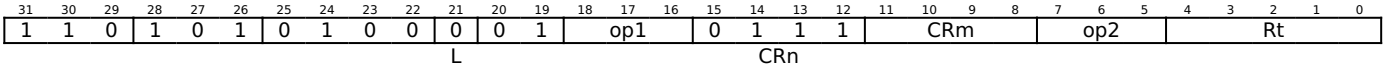
IC

Instruction cache operation

For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions*.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
IC <ic_op>{, <Xt>}
```

is equivalent to

```
SYS #<op1>, C7, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_IC`.

Assembler Symbols

<ic_op> Is an IC operation name, as listed for the IC system instruction pages, encoded in “(op1 :: CRm :: op2)”:

op1	CRm	op2	<ic_op>	Description
000	0001	000	IALLUIS	For more information, see IC IALLUIS.
000	0101	000	IALLU	For more information, see IC IALLU.
011	0101	001	IVAU	For more information, see IC IVAU.

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

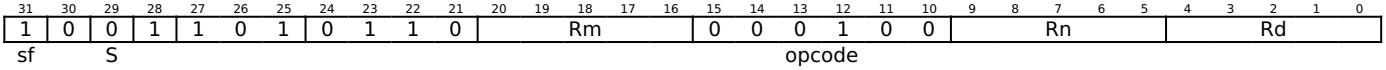
IRG

Insert random tag

This instruction inserts a random Logical Address Tag into the address in the first source register, and writes the result to the destination register. Any tags specified in the optional second source register or in GCR_EL1.Exclude are excluded from the selection of the random Logical Address Tag.

Integer

(FEAT_MTE)



Encoding

```
IRG <Xd|SP>, <Xn|SP>{, <Xm>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field. Defaults to XZR if absent.

Operation

```
let operand : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let exclude_reg : bits(64) = X{64}(m);
let exclude : bits(16) = exclude_reg[15:0] OR GCR_EL1().Exclude;

let rtag : bits(4) = AArch64_ChooseTagOrZero(exclude);
let result : bits(64) = AArch64_AddressWithAllocationTag(operand, rtag);

if d == 31 then
    SP{64}() = result;
else
    X{64}(d) = result;
end;
```

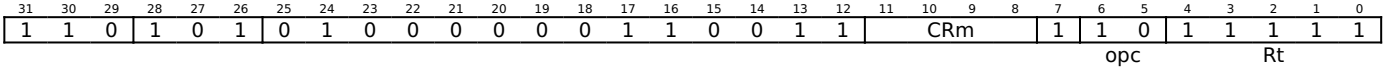
ISB

Instruction synchronization barrier

This instruction flushes the pipeline in the PE and is a context synchronization event. For more information, see *Instruction Synchronization Barrier (ISB)*.



Encoding

```
ISB {<option>|#<imm>}
```

Decode for this encoding

```
// no additional decoding required
```

Assembler Symbols

<option> Specifies an optional limitation on the barrier operation. Values are:

SY
Full system barrier operation, encoded as CRm = 0b1111. Can be omitted.

All other encodings of "CRm" are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

<imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

Operation

```
InstructionSynchronizationBarrier();

if IsFeatureImplemented(FEAT_BRBE) && BRBEBranchOnISB() then
    BRBEISB();
end;
```

LD64B

Single-copy atomic 64-byte load

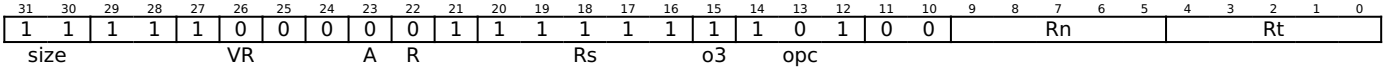
This instruction derives an address from a base register value, loads eight 64-bit doublewords from a memory location, and writes them to consecutive registers. The load starts at register Xt, with the data being read as X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt = Data[511:0]. The data is loaded atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports LD64B also supports LDA64B, ST64B, and STL64B.

For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

Integer

(FEAT_LS64)



Encoding

```
LD64B <Xt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LS64) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = FALSE;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LD64B*.

Assembler Symbols

<Xt>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
CheckLDST64BEnabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_LOAD, withstatus, acqrel, tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

data = MemLoad64B(address, accdesc);

for i = 0 to 7 do
    value = data[63+64*i : 64*i];
    if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;
    X{64}(t+i) = value;
end;
```

LDA64B

Single-copy atomic 64-byte load-acquire

This instruction derives an address from a base register value, loads eight 64-bit doublewords from a memory location, and writes them to consecutive registers. The load starts at register Xt, with the data being read as X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt = Data[511:0]. The data is loaded atomically and is required to be 64-byte aligned.

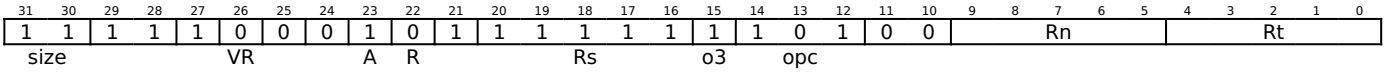
It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports LDA64B also supports LD64B, ST64B, and STL64B.

LDA64B loads from memory with acquire semantics.

For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

Integer

(FEAT_LS64 && FEAT_LSC64B)



Encoding

```
LDA64B <Xt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSC64B) then EndOfDecode(Decode_UNDEF); end;
if !IsFeatureImplemented(FEAT_LS64) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = FALSE;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = TRUE;
```

LDA64B has the same CONSTRAINED UNPREDICTABLE behavior as LD64B. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LD64B*.

Assembler Symbols

<Xt>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
CheckLDST64BEnabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_LOAD, withstatus, acqrel, tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

data = MemLoad64B(address, accdesc);

for i = 0 to 7 do
    value = data[63+64*i : 64*i];
    if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;
    X{64}(t+i) = value;
end;
```

LDADD, LDADDA, LDADDAL, LDADDL

Atomic add on word or doubleword

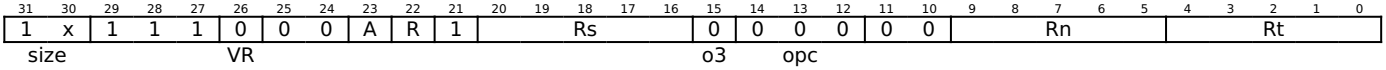
This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDADDA` and `LDADDAL` load from memory with acquire semantics.
- `LDADDL` and `LDADDAL` store to memory with release semantics.
- `LDADD` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STADD, STADDL.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && A == 0 && R == 0)`

```
LDADD <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire variant

Applies when `(size == 10 && A == 1 && R == 0)`

```
LDADDA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire-release variant

Applies when `(size == 10 && A == 1 && R == 1)`

```
LDADDAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit release variant

Applies when `(size == 10 && A == 0 && R == 1)`

```
LDADDL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && A == 0 && R == 0)`

```
LDADD <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire variant

Applies when `(size == 11 && A == 1 && R == 0)`

```
LDADDA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire-release variant

Applies when `(size == 11 && A == 1 && R == 1)`

```
LDADDAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit release variant

Applies when `(size == 11 && A == 0 && R == 1)`

```
LDADDL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 8 << UInt(size);
let regsize : integer{} = if datasize == 64 then 64 else 32;

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Alias Conditions

Alias	Is preferred when
STADD, STADDL	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_ADD, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(datasize) = ARBITRARY : bits(datasize); // Irrelevant when not executing CAS
let value : bits(datasize) = X{datasize}(s);
let data : bits(datasize) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{regsize}(t) = ZeroExtend{regsize}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDADDB, LDADDAB, LDADDALB, LDADDLB

Atomic add on byte

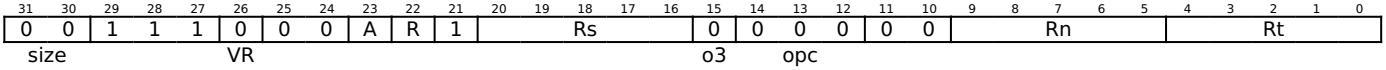
This instruction atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDADDAB` and `LDADDALB` load from memory with acquire semantics.
- `LDADDLB` and `LDADDALB` store to memory with release semantics.
- `LDADDB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STADDB, STADDLB.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDADDB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDADDAB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDADDALB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDADDLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STADDB, STADDLB	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_ADD, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(8) = ARBITRARY : bits(8); // Irrelevant when not executing CAS
let value : bits(8) = X{8}(s);
let data : bits(8) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{32}(t) = ZeroExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDADDH, LDADDAH, LDADDALH, LDADDLH

Atomic add on halfword

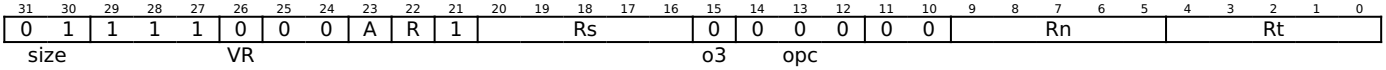
This instruction atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDADDAH` and `LDADDALH` load from memory with acquire semantics.
- `LDADDLH` and `LDADDALH` store to memory with release semantics.
- `LDADDH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STADDH, STADDLH.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDADDH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDADDAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDADDALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDADDLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STADDH, STADDLH	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_ADD, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(16) = ARBITRARY : bits(16); // Irrelevant when not executing CAS
let value : bits(16) = X{16}(s);
let data : bits(16) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{32}(t) = ZeroExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAP

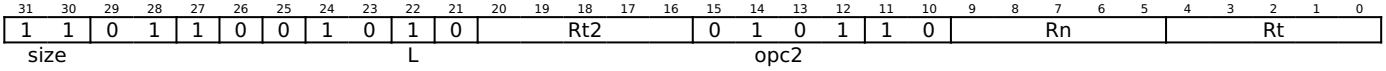
Load-acquire pair of registers

This instruction calculates an address from a base register value, loads two 64-bit doublewords from memory, and writes them to two registers. Explicit Memory effects produced by this instruction have Acquire semantics. For information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

No offset

(FEAT_LSCP)



Encoding

```
LDAP <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSCP) then EndOfDecode(Decode_UNDEF); end;

let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let acquire : boolean = TRUE;
let tagchecked : boolean = n != 31;
let ispair : boolean = TRUE;
var rt_unknown : boolean = FALSE;

if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // Result is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDP and LDIAPP*, which applies when t==t2.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
var data1 : bits(64);
var data2 : bits(64);
let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_LOAD, tagchecked, ispair,
                                                     acquire, t, t2);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let full_data : bits(128) = Mem{128}(address, accdesc);
if BigEndian(accdesc.acctype) then
    data2 = full_data[63:0];
    data1 = full_data[127:64];
else
    data1 = full_data[63:0];
    data2 = full_data[127:64];
end;

if rt_unknown then
    data1 = ARBITRARY : bits(64);
    data2 = ARBITRARY : bits(64);
end;

X{64}(t) = data1;
X{64}(t2) = data2;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPR

Load-acquire RCpc register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

`LDAPR` loads from memory with AcquirePC semantics.

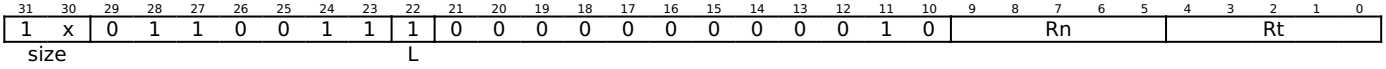
For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 2 classes: Post-index and No offset

Post-index

(FEAT_LRCPC3)



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDAPR <Wt>, [<Xn|SP>], #4
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDAPR <Xt>, [<Xn|SP>], #8
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC3) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
var wback : boolean = TRUE;
let acquirepc : boolean = TRUE;
let regsize : integer{} = if size == '11' then 64 else 32;
let datasize : integer{} = 8 << UInt(size);
let offset : integer = 1 << UInt(size);

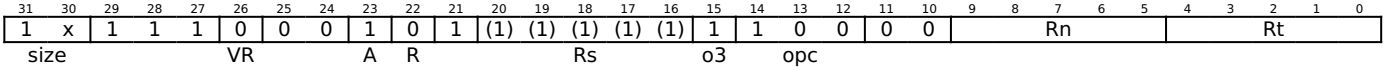
let tagchecked : boolean = TRUE;

var wb_unknown : boolean = FALSE;

if n == t && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;        // writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;    // writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

No offset

(FEAT_LRCPC)



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDAPR <Wt>, [<Xn|SP> {, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDAPR <Xt>, [<Xn|SP> {, #0}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let wback : boolean = FALSE;
let acquirepc : boolean = TRUE;
let regsize : integer{} = if size == '11' then 64 else 32;
let datasize : integer{} = 8 << UInt(size);
let offset : integer = 0;

let tagchecked : boolean = n != 31;

let wb_unknown : boolean = FALSE;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Operation

```
var address : bits(64);
var data : bits(datasize);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

data = Mem{datasize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    else
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPRB

Load-acquire RCpc register byte

This instruction derives an address from a base register value, loads a byte from the derived address in memory, zero-extends it and writes it to a register.

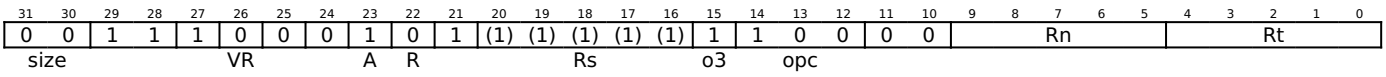
`LDAPRB` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Integer

(FEAT_LRCPC)



Encoding

```
LDAPRB <Wt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let acquirepc : boolean = TRUE;

let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
var data : bits(8);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

data = Mem{8}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPRH

Load-acquire RCpc register halfword

This instruction derives an address from a base register value, loads a halfword from the derived address in memory, zero-extends it and writes it to a register.

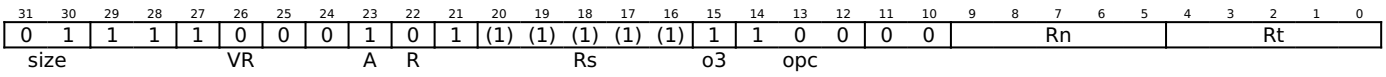
`LDAPRH` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Integer

(FEAT_LRCPC)



Encoding

```
LDAPRH <Wt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let acquirepc : boolean = TRUE;

let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
var data : bits(16);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

data = Mem{16}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPUR

Load-acquire RCpc register (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a 32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register.

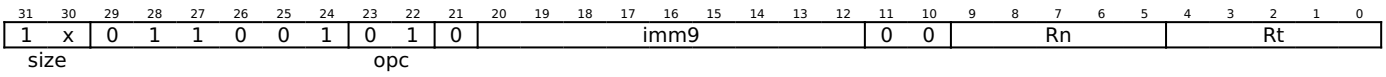
`LDAPUR` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDAPUR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDAPUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 8 << scale;
let regsize : integer{} = if datasize == 64 then 64 else 32;
let acquirepc : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPURB

Load-acquire RCpc register byte (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a byte from memory, zero-extends it, and writes it to a register.

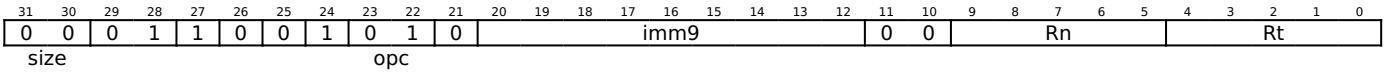
`LDAPURB` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding

```
LDAPURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 8;
let acquirepc : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPURH

Load-acquire RCpc register halfword (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a halfword from memory, zero-extends it, and writes it to a register.

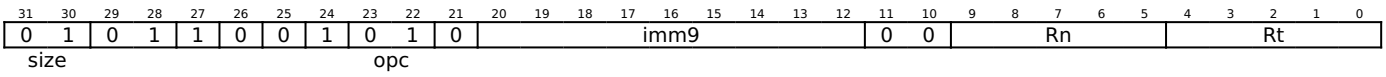
`LDAPURH` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding

```
LDAPURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 16;
let acquirepc : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPURSB

Load-acquire RCpc register signed byte (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed byte from memory, sign-extends it, and writes it to a register.

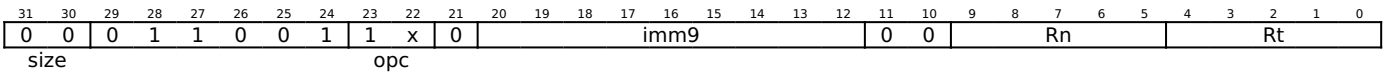
`LDAPURSB` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDAPURSB <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDAPURSB <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 8;
let regsize : integer{} = 64 >> UInt(opc[0]);
let acquirepc : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPURSH

Load-acquire RCpc register signed halfword (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed halfword from memory, sign-extends it, and writes it to a register.

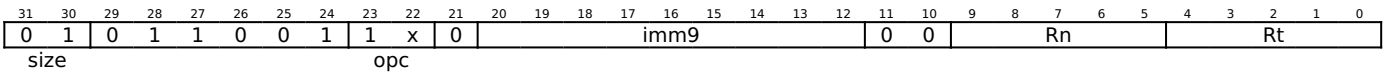
`LDAPURSH` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDAPURSH <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDAPURSH <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 16;
let regsize : integer{} = 64 >> UInt(opc[0]);
let acquirepc : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAPURSW

Load-acquire RCpc register signed word (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register.

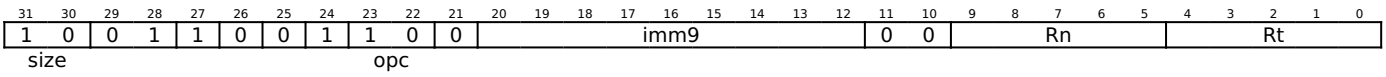
`LDAPURSW` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding

```
LDAPURSW <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32;
let acquirepc : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLDAcqPC(tagchecked, acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{64}(t) = SignExtend{64}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

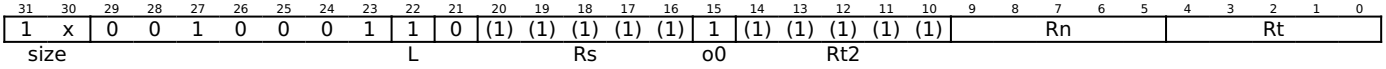
LDAR

Load-acquire register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. `LDAR` loads from memory with Acquire semantics.
For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDAR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDAR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 8 << UInt(size);
let regsize : integer{} = if datasize == 64 then 64 else 32;
let acquire : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_LOAD, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

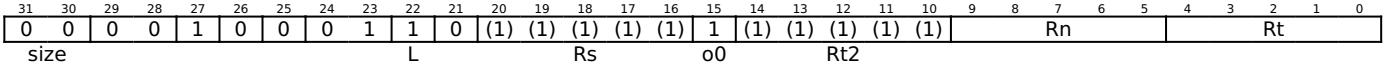
LDARB

Load-acquire register byte

This instruction derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register.
`LDARB` loads from memory with Acquire semantics.
For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDARB <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_LOAD, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let data : bits(8) = Mem{8}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

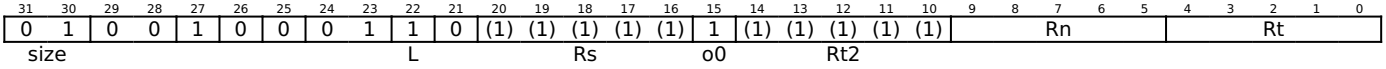
LDARH

Load-acquire register halfword

This instruction derives an address from a base register value, loads a halfword from memory, zero-extends it, and writes it to a register. `LDARH` loads from memory with Acquire semantics.
For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDARH <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_LOAD, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let data : bits(16) = Mem{16}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDATXR

Load-acquire unprivileged exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

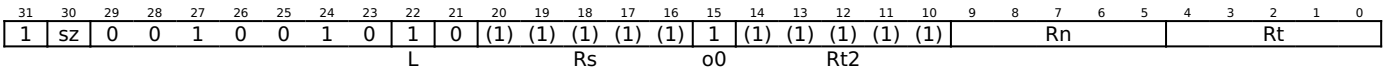
Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `LDATXR` is equivalent to `LDXR`.

For information about addressing modes, see *Load/Store addressing modes*.

No offset

(FEAT_LSUI)



Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
LDATXR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
LDATXR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let regsize : integer{} = if elsize == 64 then 64 else 32;
let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem{elsize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAXP

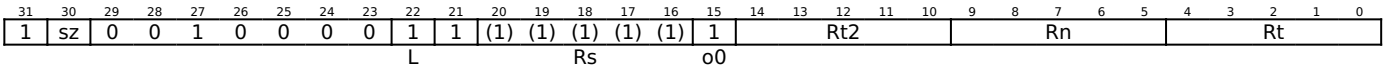
Load-acquire exclusive pair of registers

This instruction derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*.

`LDAXP` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
LDAXP <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
LDAXP <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let datasize : integer{} = elsize * 2;
let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;    // result is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs* and *LDAXP*.

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Operation

```
var address : bits(64);
var data : bits(datasize);

let dbytes : integer{} = datasize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
// When elsize is 32, the access is single-copy atomic
let ispair : boolean = elsize == 64;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, ispair, t, t2);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem{datasize}(address, accdesc);
if rt_unknown then
    // ConstrainedUNPREDICTABLE case
    X{datasize}(t)  = ARBITRARY : bits(datasize);        // In this case t = t2
elsif BigEndian(accdesc.acctype) then
    X{elsize}(t)  = data[elsize +: elsize];
    X{elsize}(t2) = data[0 +: elsize];
else
    X{elsize}(t)  = data[0 +: elsize];
    X{elsize}(t2) = data[elsize +: elsize];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAXR

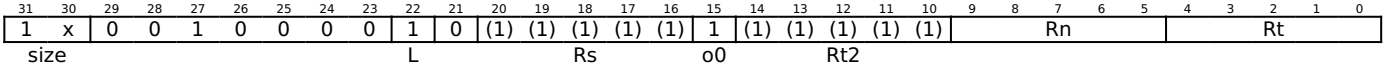
Load-acquire exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*.

`LDAXR` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDAXR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDAXR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 8 << UInt(size);
let regsize : integer{} = if elsize == 64 then 64 else 32;
let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem{elsize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAXRB

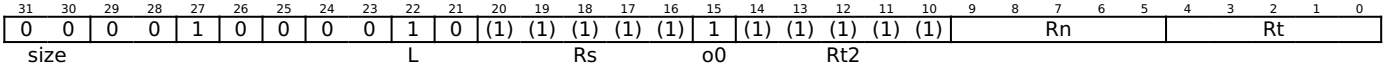
Load-acquire exclusive register byte

This instruction derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*.

`LDAXRB` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDAXRB <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
var data : bits(8);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, 1, accdesc);

data = Mem{8}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDAXRH

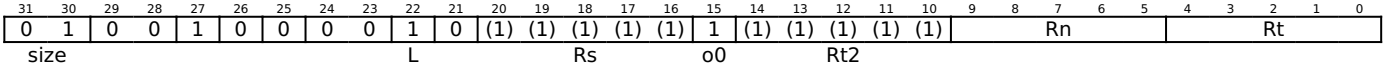
Load-acquire exclusive register halfword

This instruction derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*.

`LDAXRH` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see *Load-Acquire, Load-AcquirePC, and Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDAXRH <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
var data : bits(16);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, 2, accdesc);

data = Mem{16}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDCLR, LDCLRA, LDCLRAL, LDCLRL

Atomic bit clear on word or doubleword

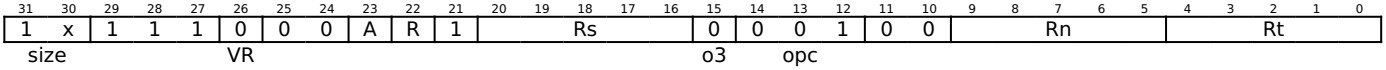
This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDCLRA` and `LDCLRAL` load from memory with acquire semantics.
- `LDCLRL` and `LDCLRAL` store to memory with release semantics.
- `LDCLR` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STCLR, STCLRL.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && A == 0 && R == 0)`

```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Alias Conditions

Alias	Is preferred when
STCLR, STCLRL	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_BIC, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(datasize) = ARBITRARY : bits(datasize); // Irrelevant when not executing CAS
let value : bits(datasize) = X{datasize}(s);
let data : bits(datasize) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{regsize}(t) = ZeroExtend{regsize}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB

Atomic bit clear on byte

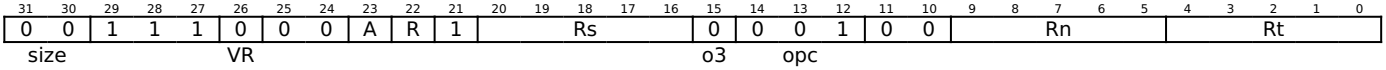
This instruction atomically loads an 8-bit byte from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDCLRAB` and `LDCLRALB` load from memory with acquire semantics.
- `LDCLRLB` and `LDCLRALB` store to memory with release semantics.
- `LDCLRB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STCLRB, STCLRLB.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDCLRB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDCLRAB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDCLRALB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDCLRLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STCLRB, STCLRLB	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_BIC, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(8) = ARBITRARY : bits(8); // Irrelevant when not executing CAS
let value : bits(8) = X{8}(s);
let data : bits(8) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{32}(t) = ZeroExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH

Atomic bit clear on halfword

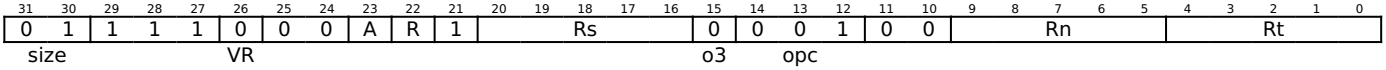
This instruction atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDCLRAH` and `LDCLRALH` load from memory with acquire semantics.
- `LDCLRLH` and `LDCLRALH` store to memory with release semantics.
- `LDCLRH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STCLRH, STCLRLH.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDCLRH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDCLRAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDCLRALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDCLRLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STCLRH, STCLRLH	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_BIC, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();

LDCLRP, LDCLRPA, LDCLRPAL, LDCLRPL

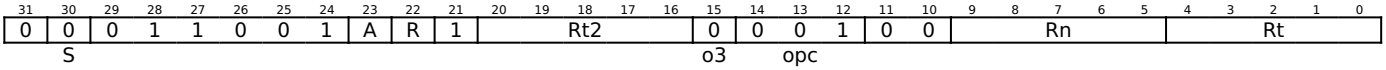
Atomic bit clear on quadword

This instruction atomically loads a 128-bit quadword from memory, performs a bitwise AND with the complement of the value held in a pair of registers on it, and stores the result back to memory. The value initially loaded from memory is returned in the same pair of registers.

- `LDCLRPA` and `LDCLRPAL` load from memory with acquire semantics.
- `LDCLRPL` and `LDCLRPAL` store to memory with release semantics.
- `LDCLRP` has neither acquire nor release semantics.

Integer

(FEAT_LSE128)



Encoding for the LDCLRP variant

Applies when `(A == 0 && R == 0)`

```
LDCLRP <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the LDCLRPA variant

Applies when `(A == 1 && R == 0)`

```
LDCLRPA <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the LDCLRPAL variant

Applies when `(A == 1 && R == 1)`

```
LDCLRPAL <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the LDCLRPL variant

Applies when `(A == 0 && R == 1)`

```
LDCLRPL <Xt1>, <Xt2>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE128) then EndOfDecode(Decode_UNDEF); end;
if Rt  == '11111' then EndOfDecode(Decode_UNDEF); end;
if Rt2 == '11111' then EndOfDecode(Decode_UNDEF); end;

let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let acquire : boolean = A == '1';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;

if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LSE128OVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // result is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *128-bit Atomic Memory Operations*.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

LDEORH, LDEORAH, LDEORALH, LDEORLH

Atomic exclusive-OR on halfword

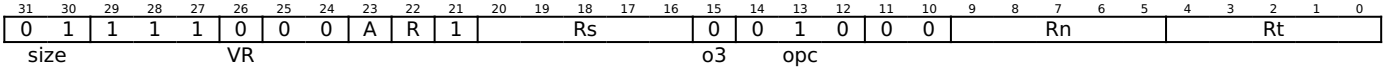
This instruction atomically loads a 16-bit halfword from memory, performs an exclusive-OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDEORAH` and `LDEORALH` load from memory with acquire semantics.
- `LDEORLH` and `LDEORALH` store to memory with release semantics.
- `LDEORH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STEORH, STEORLH.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDEORH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDEORAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDEORALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDEORLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STEORH, STEORLH	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_EOR, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(16) = ARBITRARY : bits(16); // Irrelevant when not executing CAS

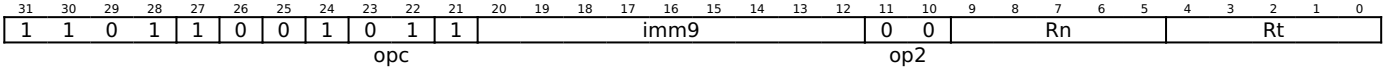
LDG

Load Allocation Tag

This instruction loads an Allocation Tag from a memory address, generates a Logical Address Tag from the Allocation Tag and merges it into the destination register. The address used for the load is calculated from the base register and an immediate signed offset scaled by the Tag Granule.

Integer

(FEAT_MTE)



Encoding

```
LDG <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate offset, a multiple of 16 in the range -4096 to 4080, defaulting to 0 and encoded in the "imm9" field.

Operation

```
var address : bits(64);
var tag : bits(4);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

LDGM

Load tag multiple

This instruction reads a naturally aligned block of N Allocation Tags, where the size of N is identified in GMID_EL1.BS, and writes the Allocation Tag read from address A to the destination register at 4*A<7:4>+3:4*A<7:4>. Bits of the destination register not written with an Allocation Tag are set to 0.

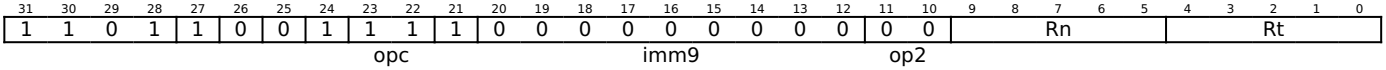
If the value of HCR_EL2.TGE is 0 and the Effective value of SCTLR2_EL1.GM0 is 0, this instruction is UNDEFINED at EL0.

If the value of HCR_EL2.TGE is 1 and the Effective value of SCTLR2_EL2.GM0 is 0, this instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

Integer

(FEAT_MTE2)



Encoding

```
LDGM <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE2) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
if PSTATE.EL == EL0 && !IsGMEnabledAtEL0() then Undefined(); end;

var data : bits(64) = Zeros{};
var address : bits(64);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let size : integer{} = 4 * 2 ^ UInt(GMID_EL1().BS);
address = AlignDownSize(address, size);
let count : integer = size >> LOG2_TAG_GRANULE;
var index : integer = UInt(address[LOG2_TAG_GRANULE+3:LOG2_TAG_GRANULE]);
let stzgm : boolean = FALSE;
let accdesc : AccessDescriptor = CreateAccDescLDGSTG(MemOp_LOAD, stzgm, t);

for i = 0 to count-1 do
    let tag : bits(4) = AArch64_MemTag(address, accdesc);
    data[index*:4] = tag;
    address = AddressIncrement(address, TAG_GRANULE, accdesc);
    index = index + 1;
end;

X{64}(t) = data;
```

LDIAPP

Load-Acquire RCpc ordered pair of registers

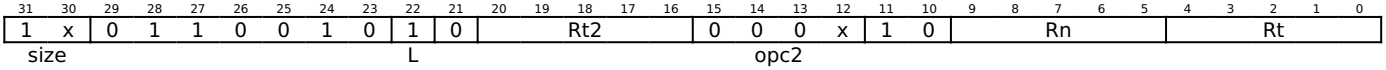
This instruction calculates an address from a base register value and an optional offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The instruction also has memory ordering semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, with the additional requirement that:

- The Memory effects associated with Xt1/Wt1 are Ordered-before the Memory effects associated with Xt2/Wt2.
- `LDIAPP` loads from memory with Acquire semantics.

For information about addressing modes, see *Load/Store addressing modes*.

Integer

(FEAT_LRCPC3)



Encoding for the 32-bit post-index variant

Applies when `(size == 10 && opc2 == 0000)`

```
LDIAPP <Wt1>, <Wt2>, [<Xn|SP>], #8
```

Encoding for the 32-bit variant

Applies when `(size == 10 && opc2 == 0001)`

```
LDIAPP <Wt1>, <Wt2>, [<Xn|SP>]
```

Encoding for the 64-bit post-index variant

Applies when `(size == 11 && opc2 == 0000)`

```
LDIAPP <Xt1>, <Xt2>, [<Xn|SP>], #16
```

Encoding for the 64-bit variant

Applies when `(size == 11 && opc2 == 0001)`

```
LDIAPP <Xt1>, <Xt2>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC3) then EndOfDecode(Decode_UNDEF); end;
let ispair : boolean = TRUE;
let postindex : boolean = opc2[0] == '0';
var wback : boolean = opc2[0] == '0';
```

`LDIAPP` has the same CONSTRAINED UNPREDICTABLE behavior as `LDP`. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDP and LDIAPP*.

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

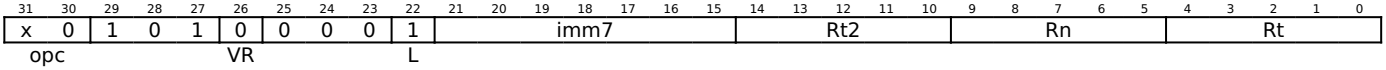
LDNP

Load pair of registers, with non-temporal hint

This instruction calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers.

For information about addressing modes, see *Load/Store addressing modes*. For information about non-temporal pair instructions, see *Load/Store non-temporal pair*.



Encoding for the 32-bit variant

Applies when `(opc == 00)`

```
LDNP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = TRUE;
let scale : integer{} = 2 + UInt(opc[1]);
let datasize : integer{} = 8 << scale;
let offset : bits(64) = LSL(SignExtend{64}(imm7), scale);
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // Result is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDNP*.

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the "32-bit" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. For the "64-bit" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Operation

```
var address : bits(64);
let privileged : boolean = PSTATE.EL != EL0;
let ispair : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, ispair, t, t2);
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);
let data : bits(2*datasize) = Mem{2*datasize}(address, accdesc);
if rt_unknown then
    X{datasize}(t) = ARBITRARY : bits(datasize);

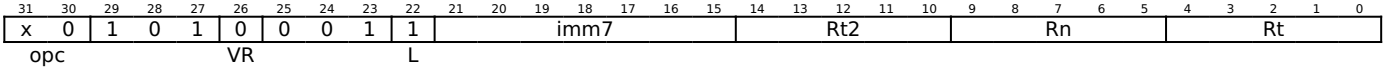
LDP

Load pair of registers

This instruction calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index



Encoding for the 32-bit variant

Applies when (opc == 00)

```
LDP <Wt1>, <Wt2>, [<Xn|SP>], #<imm>
```

Encoding for the 64-bit variant

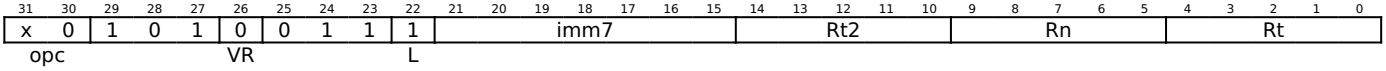
Applies when (opc == 10)

```
LDP <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
```

Pre-index



Encoding for the 32-bit variant

Applies when (opc == 00)

```
LDP <Wt1>, <Wt2>, [<Xn|SP>, #<imm>]!
```

Encoding for the 64-bit variant

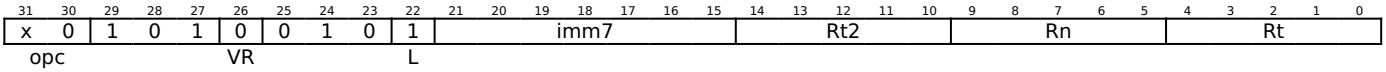
Applies when (opc == 10)

```
LDP <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
```

Signed offset



Encoding for the 32-bit variant

Applies when (opc == 00)

```
LDP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant

Applies when (opc == 10)

```
LDP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDP*.

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the "Post-index 32-bit" and "Pre-index 32-bit" variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4. For the "Post-index 64-bit" and "Pre-index 64-bit" variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8. For the "Signed offset 32-bit" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. For the "Signed offset 64-bit" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

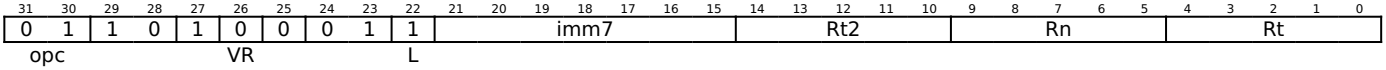
LDPSW

Load pair of registers signed word

This instruction calculates an address from a base register value and an immediate offset, loads two 32-bit words from memory, sign-extends them, and writes them to two registers. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index



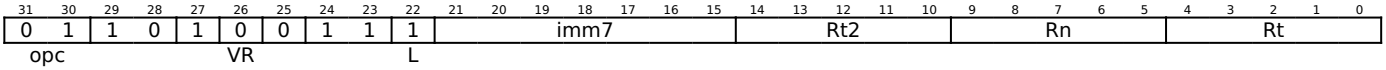
Encoding

```
LDPSW <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
```

Pre-index



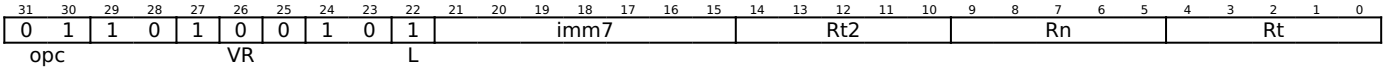
Encoding

```
LDPSW <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
```

Signed offset



Encoding

```
LDPSW <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDPSW*.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the "Post-index" and "Pre-index" variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4. For the "Signed offset" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

Shared Decode

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let scale : integer{} = 2 + UInt(opc[1]);
let datasize : integer{} = 32;
let offset : bits(64) = LSL(SignExtend{64}(imm7), scale);
let tagchecked : boolean = wback || n != 31;

var rt_unknown : boolean = FALSE;
var wb_unknown : boolean = FALSE;

if wback && (t == n || t2 == n) && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;        // Writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;    // Writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;

if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // Result is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```

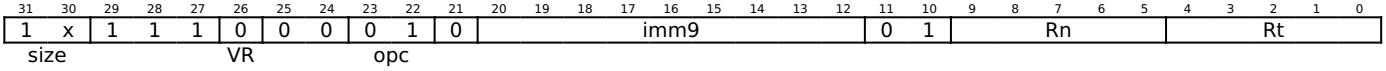
LDR (immediate)

Load register (immediate)

This instruction loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDR <Wt>, [<Xn|SP>], #<simm>
```

Encoding for the 64-bit variant

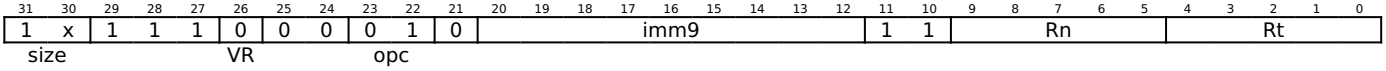
Applies when `(size == 11)`

```
LDR <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDR <Wt>, [<Xn|SP>, #<simm>]!
```

Encoding for the 64-bit variant

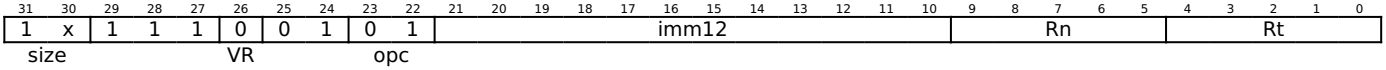
Applies when `(size == 11)`

```
LDR <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDR <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDR <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
let scale : integer{} = UInt(size);
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), scale);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDR (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<pimm>	For the "32-bit" variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4. For the "64-bit" variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 8 << scale;
let regsize : integer{} = if datasize == 64 then 64 else 32;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var wb_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);

if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

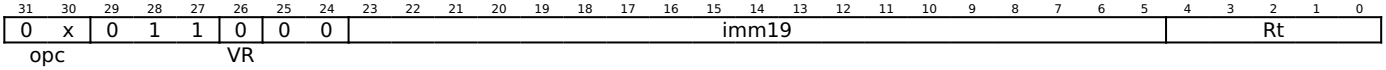
LDR (literal)

Load register (literal)

This instruction calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(opc == 00)`

```
LDR <Wt>, <label>
```

Encoding for the 64-bit variant

Applies when `(opc == 01)`

```
LDR <Xt>, <label>
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let size : integer{} = 4 << UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = FALSE;

let offset : bits(64) = SignExtend{}(imm19::'00');
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<label>	Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Operation

```
let address : bits(64) = PC64() + offset;
let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

X{size * 8}(t) = Mem{size * 8}(address, accdesc);
```

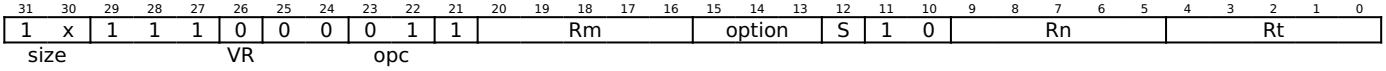
LDR (register)

Load register (register)

This instruction calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted and extended. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDR <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let scale : integer{} = UInt(size);
let shift : integer{} = if S == '1' then scale else 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> For the "32-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#2

For the "64-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#3

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 8 << scale;
let regsize : integer{} = if datasize == 64 then 64 else 32;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDRAA, LDRAB

Load register, with pointer authentication

This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

Key A is used for `LDRAA`. Key B is used for `LDRAB`.

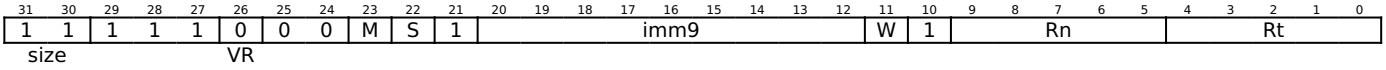
If the authentication passes, the PE behaves the same as for an `LDR` instruction. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about addressing modes, see *Load/Store addressing modes*.

PAC

(FEAT_PAuth)



Encoding for the Key A, offset variant

Applies when `(M == 0 && W == 0)`

```
LDRAA <Xt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the Key A, pre-indexed variant

Applies when `(M == 0 && W == 1)`

```
LDRAA <Xt>, [<Xn|SP>{, #<simm>}]!
```

Encoding for the Key B, offset variant

Applies when `(M == 1 && W == 0)`

```
LDRAB <Xt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the Key B, pre-indexed variant

Applies when `(M == 1 && W == 1)`

```
LDRAB <Xt>, [<Xn|SP>{, #<simm>}]!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
var wback : boolean = W == '1';
let use_key_a : boolean = M == '0';
let S10 : bits(10) = S::imm9;
let offset : bits(64) = LSL(SignExtend{64}(S10), 3);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var wb_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;       // writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;   // writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, a multiple of 8 in the range -4096 to 4088, defaulting to 0 and encoded in the "S:imm9" field as <simm>/8.

Operation

```
var address : bits(64);
let privileged : boolean = PSTATE.EL != EL0;
let auth_then_branch : boolean = TRUE;

let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);
if n == 31 then
    address = SP{64}();
else
    address = X{64}(n);
end;

if use_key_a then
    address = AuthDA(address, X{64}(31), auth_then_branch);
else
    address = AuthDB(address, X{64}(31), auth_then_branch);
end;

if n == 31 then
    CheckSPAlignment();
end;

address = AddressAdd(address, offset, accdesc);
X{64}(t) = Mem{64}(address, accdesc);

if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

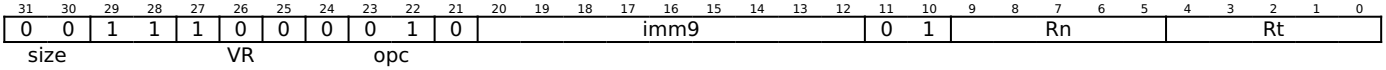
LDRB (immediate)

Load register byte (immediate)

This instruction loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



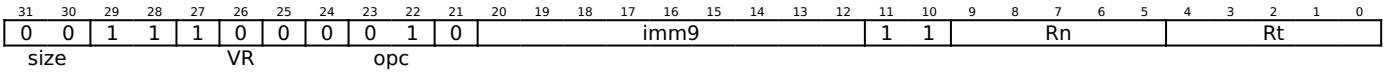
Encoding

```
LDRB <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



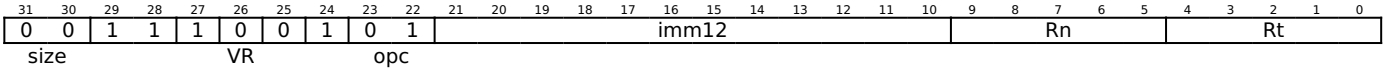
Encoding

```
LDRB <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding

```
LDRB <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 0);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRB (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var wb_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

let data : bits(8) = Mem{8}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);

if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

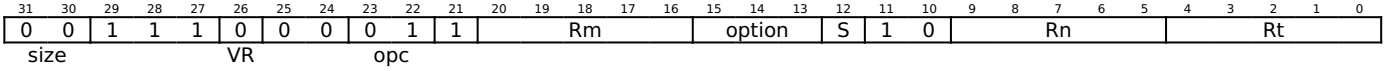
This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

LDRB (register)

Load register byte (register)

This instruction calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the Extended register variant

Applies when `(option != 011)`

```
LDRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the Shifted register variant

Applies when `(option == 011)`

```
LDRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW
110	SXTW
111	SXTX

<amount> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

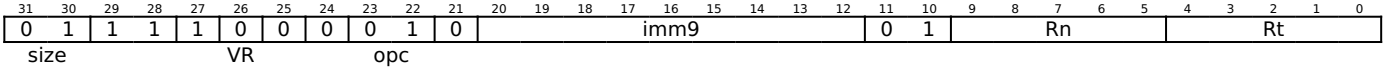
LDRH (immediate)

Load register halfword (immediate)

This instruction loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



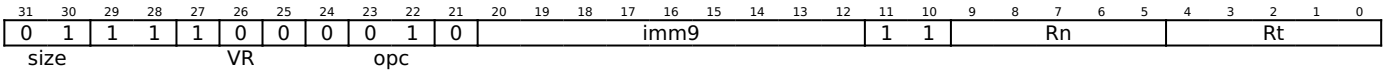
Encoding

```
LDRH <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



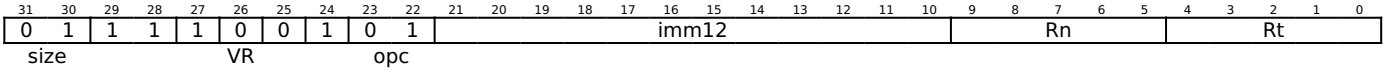
Encoding

```
LDRH <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding

```
LDRH <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 1);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRH (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var wb_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

let data : bits(16) = Mem{16}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);

if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

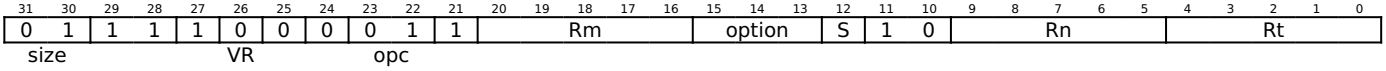
LDRH (register)

Load register halfword (register)

This instruction calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#1

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(16) = Mem{16}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

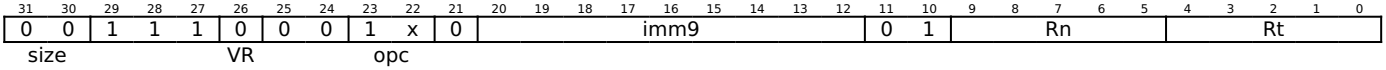
LDRSB (immediate)

Load register signed byte (immediate)

This instruction loads a byte from memory, sign-extends it to either 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSB <Wt>, [<Xn|SP>], #<simm>
```

Encoding for the 64-bit variant

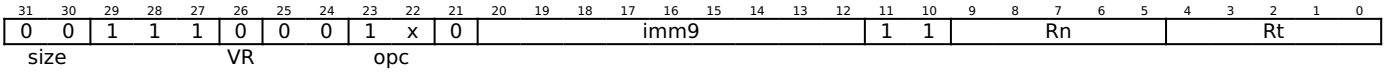
Applies when `(opc == 10)`

```
LDRSB <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSB <Wt>, [<Xn|SP>, #<simm>]!
```

Encoding for the 64-bit variant

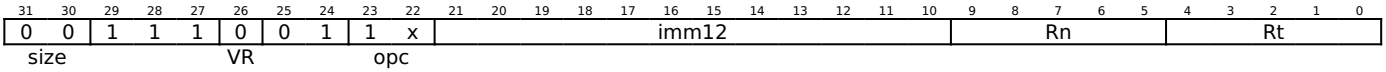
Applies when `(opc == 10)`

```
LDRSB <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSB <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDRSB <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 0);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSB (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<pimm>	Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var wb_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

let data : bits(8) = Mem{8}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);

if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

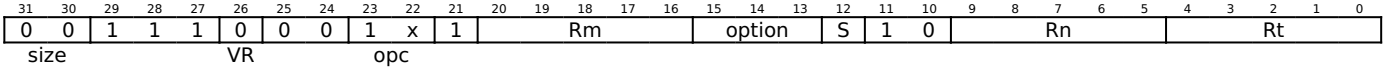
LDRSB (register)

Load register signed byte (register)

This instruction calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit with extended register offset variant

Applies when `(opc == 11 && option != 011)`

```
LDRSB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the 32-bit with shifted register offset variant

Applies when `(opc == 11 && option == 011)`

```
LDRSB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Encoding for the 64-bit with extended register offset variant

Applies when `(opc == 10 && option != 011)`

```
LDRSB <Xt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the 64-bit with shifted register offset variant

Applies when `(opc == 10 && option == 011)`

```
LDRSB <Xt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = 0;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm>	When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm>	When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
<extend>	Is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW
110	SXTW
111	SXTX

<amount>	Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(8) = Mem{8}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

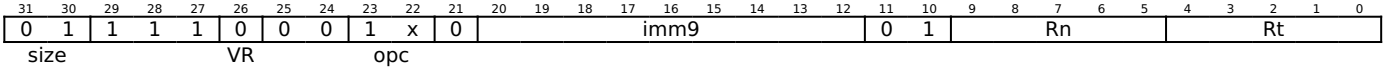
LDRSH (immediate)

Load register signed halfword (immediate)

This instruction loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSH <Wt>, [<Xn|SP>], #<simm>
```

Encoding for the 64-bit variant

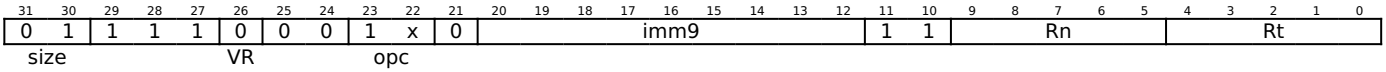
Applies when `(opc == 10)`

```
LDRSH <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSH <Wt>, [<Xn|SP>, #<simm>]!
```

Encoding for the 64-bit variant

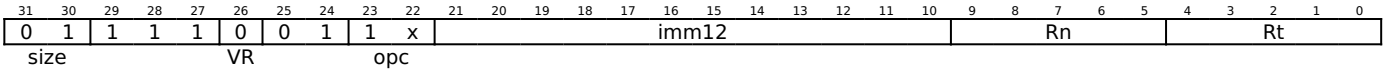
Applies when `(opc == 10)`

```
LDRSH <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSH <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDRSH <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 1);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSH (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var wb_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

let data : bits(16) = Mem{16}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);

if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

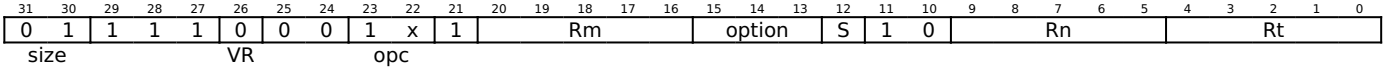
LDRSH (register)

Load register signed halfword (register)

This instruction calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDRSH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDRSH <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#1

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(16) = Mem{16}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

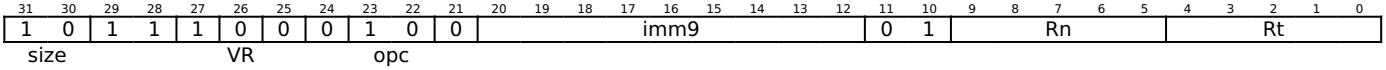
LDRSW (immediate)

Load register signed word (immediate)

This instruction loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



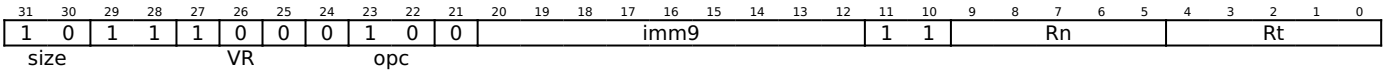
Encoding

```
LDRSW <Xt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



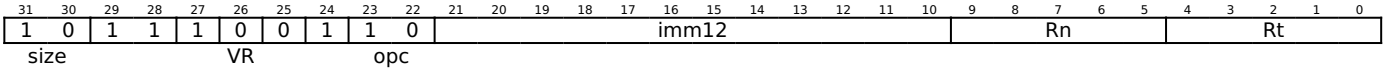
Encoding

```
LDRSW <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
var wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding

```
LDRSW <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
var wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 2);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSW (immediate)*.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var wb_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS => wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN =>    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

let data : bits(32) = Mem{32}(address, accdesc);
X{64}(t) = SignExtend{64}(data);

if wback then
    if wb_unknown then
        address = ARBITRARY : bits(64);
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

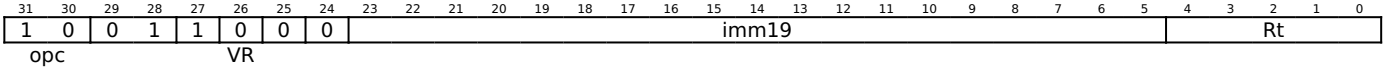
LDRSW (literal)

Load register signed word (literal)

This instruction calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDRSW <Xt>, <label>
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = FALSE;

let offset : bits(64) = SignExtend{}(imm19::'00');
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<label>	Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
let address : bits(64) = PC64() + offset;
let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

let data : bits(32) = Mem{32}(address, accdesc);
X{64}(t) = SignExtend{64}(data);
```

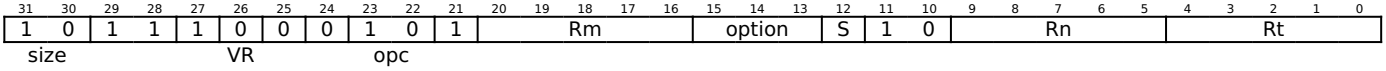
LDRSW (register)

Load register signed word (register)

This instruction calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDRSW <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 2 else 0;
```

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#2

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(32) = Mem{32}(address, accdesc);
X{64}(t) = SignExtend{64}(data);
```

LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword

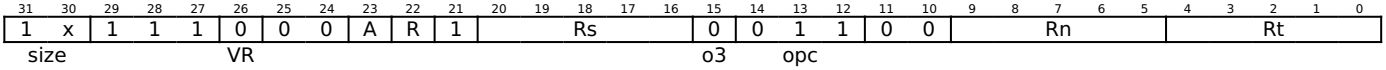
This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDSETA` and `LDSETAL` load from memory with acquire semantics.
- `LDSETL` and `LDSETAL` store to memory with release semantics.
- `LDSET` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STSET, STSETL.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && A == 0 && R == 0)`

```
LDSET <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire variant

Applies when `(size == 10 && A == 1 && R == 0)`

```
LDSETA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire-release variant

Applies when `(size == 10 && A == 1 && R == 1)`

```
LDSETAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit release variant

Applies when `(size == 10 && A == 0 && R == 1)`

```
LDSETL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && A == 0 && R == 0)`

```
LDSET <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire variant

Applies when `(size == 11 && A == 1 && R == 0)`

```
LDSETA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire-release variant

Applies when `(size == 11 && A == 1 && R == 1)`

```
LDSETAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit release variant

Applies when `(size == 11 && A == 0 && R == 1)`

```
LDSETL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 8 << UInt(size);
let regsize : integer{} = if datasize == 64 then 64 else 32;

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Alias Conditions

Alias	Is preferred when
STSET, STSETL	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_ORR, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(datasize) = ARBITRARY : bits(datasize); // Irrelevant when not executing CAS
let value : bits(datasize) = X{datasize}(s);
let data : bits(datasize) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{regsize}(t) = ZeroExtend{regsize}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDSETB, LDSETAB, LDSETALB, LDSETLB

Atomic bit set on byte

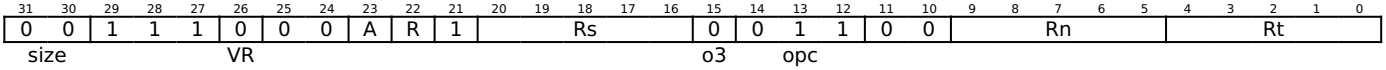
This instruction atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDSETAB` and `LDSETALB` load from memory with acquire semantics.
- `LDSETLB` and `LDSETALB` store to memory with release semantics.
- `LDSETB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STSETB, STSETLB.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDSETB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDSETAB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDSETALB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDSETLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STSETB, STSETLB	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_ORR, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then

LDSETH, LDSETAH, LDSETALH, LDSETLH

Atomic bit set on halfword

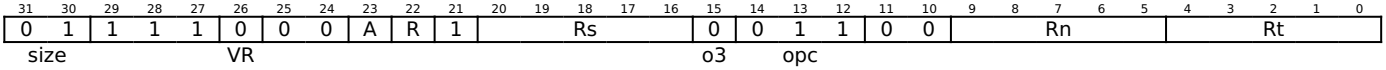
This instruction atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDSETAH` and `LDSETALH` load from memory with acquire semantics.
- `LDSETLH` and `LDSETALH` store to memory with release semantics.
- `LDSETH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STSETH, STSETLH.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDSETH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDSETAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDSETALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDSETLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STSETH, STSETLH	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_ORR, acquire, release,
                                                       tagchecked, privileged, t, s);

LDSETP, LDSETPA, LDSETPAL, LDSETPL

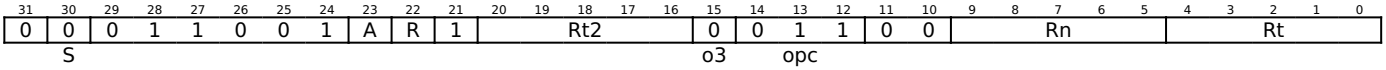
Atomic bit set on quadword

This instruction atomically loads a 128-bit quadword from memory, performs a bitwise OR with the value held in a pair of registers on it, and stores the result back to memory. The value initially loaded from memory is returned in the same pair of registers.

- `LDSETPA` and `LDSETPAL` load from memory with acquire semantics.
- `LDSETPL` and `LDSETPAL` store to memory with release semantics.
- `LDSETP` has neither acquire nor release semantics.

Integer

(FEAT_LSE128)



Encoding for the LDSETP variant

Applies when `(A == 0 && R == 0)`

```
LDSETP <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the LDSETPA variant

Applies when `(A == 1 && R == 0)`

```
LDSETPA <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the LDSETPAL variant

Applies when `(A == 1 && R == 1)`

```
LDSETPAL <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the LDSETPL variant

Applies when `(A == 0 && R == 1)`

```
LDSETPL <Xt1>, <Xt2>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE128) then EndOfDecode(Decode_UNDEF); end;
if Rt  == '11111' then EndOfDecode(Decode_UNDEF); end;
if Rt2 == '11111' then EndOfDecode(Decode_UNDEF); end;

let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let acquire : boolean = A == '1';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;

if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LSE128OVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // result is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *128-bit Atomic Memory Operations*.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
let value1 : bits(64) = X{}(t);
let value2 : bits(64) = X{}(t2);

LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL

Atomic signed maximum on word or doubleword

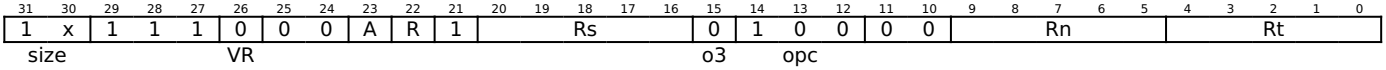
This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDSMAXA` and `LDSMAXAL` load from memory with acquire semantics.
- `LDSMAXL` and `LDSMAXAL` store to memory with release semantics.
- `LDSMAX` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STSMAX, STSMAXL.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && A == 0 && R == 0)`

```
LDSMAX <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire variant

Applies when `(size == 10 && A == 1 && R == 0)`

```
LDSMAXA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire-release variant

Applies when `(size == 10 && A == 1 && R == 1)`

```
LDSMAXAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit release variant

Applies when `(size == 10 && A == 0 && R == 1)`

```
LDSMAXL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && A == 0 && R == 0)`

```
LDSMAX <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire variant

Applies when `(size == 11 && A == 1 && R == 0)`

```
LDSMAXA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire-release variant

Applies when `(size == 11 && A == 1 && R == 1)`

```
LDSMAXAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit release variant

Applies when `(size == 11 && A == 0 && R == 1)`

```
LDSMAXL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 8 << UInt(size);
let regsize : integer{} = if datasize == 64 then 64 else 32;

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Alias Conditions

Alias	Is preferred when
STSMAX, STSMAXL	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_SMAX, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(datasize) = ARBITRARY : bits(datasize); // Irrelevant when not executing CAS
let value : bits(datasize) = X{datasize}(s);
let data : bits(datasize) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{regsize}(t) = ZeroExtend{regsize}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB

Atomic signed maximum on byte

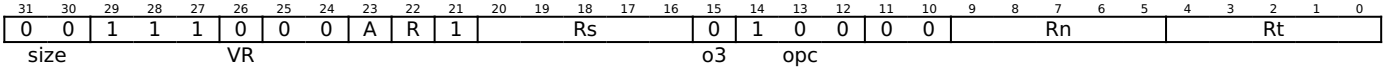
This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDSMAXAB` and `LDSMAXALB` load from memory with acquire semantics.
- `LDSMAXLB` and `LDSMAXALB` store to memory with release semantics.
- `LDSMAXB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STSMAXB, STSMAXLB.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDSMAXB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDSMAXAB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDSMAXALB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDSMAXLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STSMAXB, STSMAXLB	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_SMAX, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(8) = ARBITRARY : bits(8); // Irrelevant when not executing CAS
let value : bits(8) = X{8}(s);
let data : bits(8) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{32}(t) = ZeroExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH

Atomic signed maximum on halfword

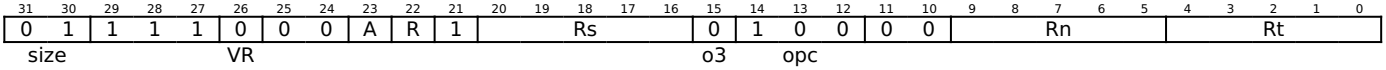
This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDSMAXAH` and `LDSMAXALH` load from memory with acquire semantics.
- `LDSMAXLH` and `LDSMAXALH` store to memory with release semantics.
- `LDSMAXH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STSMAXH, STSMAXLH.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDSMAXH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDSMAXAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDSMAXALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDSMAXLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STSMAXH, STSMAXLH	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;

LDTADD, LDTADDA, LDTADDAL, LDTADDL

Atomic add unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR, or XZR, `LDTADDA` and `LDTADDAL` load from memory with acquire semantics.
- `LDTADDL` and `LDTADDAL` store to memory with release semantics.
- `LDTADD` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.
This instruction is used by the alias STTADD, STTADDL.

Integer

LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL

Atomic bit clear unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR, or XZR, `LDTCLRA` and `LDTCLRAL` load from memory with acquire semantics.
- `LDTCLRL` and `LDTCLRAL` store to memory with release semantics.
- `LDTCLR` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.
This instruction is used by the alias STTCLR, STTCLRL.

```

Encoding for the 64-bit no memory ordering variant

Applies when `(sz == 1 && A == 0 && R == 0)`

```
LDTCLR <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire variant

Applies when `(sz == 1 && A == 1 && R == 0)`

```
LDTCLRA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire-release variant

Applies when `(sz == 1 && A == 1 && R == 1)`

```
LDTCLRAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit release variant

Applies when `(sz == 1 && A == 0 && R == 1)`

```
LDTCLRL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 32 << UInt(sz);
let regsize : integer{} = if datasize == 64 then 64 else 32;

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Alias Conditions

Alias	Is preferred when
STTCLR, STTCLRL	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_BIC, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(datasize) = ARBITRARY : bits(datasize); // Irrelevant when not executing CAS
let value : bits(datasize) = X{datasize}(s);
let data : bits(datasize) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{regsize}(t) = ZeroExtend{regsize}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

LDTNP

Load unprivileged pair of registers, with non-temporal hint

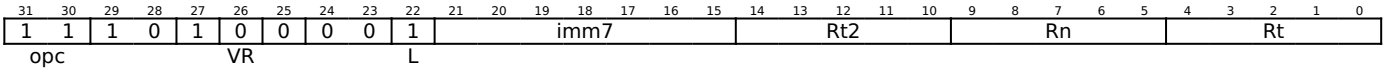
This instruction calculates an address from a base register value and an immediate offset, loads two 64-bit doublewords from memory, and writes them to two registers. For information about addressing modes, see *Load/Store addressing modes*. For information about non-temporal pair instructions, see *Load/Store non-temporal pair*.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Signed offset

(FEAT_LSUI)



Encoding

```
LDTNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = TRUE;
let datasize : integer{} = 64;
let offset : bits(64) = LSL(SignExtend{64}(imm7), 3);
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // Result is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

LDTNP has the same CONSTRAINED UNPREDICTABLE behavior as LDNP. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDNP*.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	Is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Operation

```
var address : bits(64);
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let ispair : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, ispair, t, t2);
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);
let data : bits(2*datasize) = Mem{2*datasize}(address, accdesc);
if rt_unknown then
    X{datasize}(t) = ARBITRARY : bits(datasize);
elsif BigEndian(accdesc.acctype) then
    X{datasize}(t2) = data[(datasize-1):0];
    X{datasize}(t)  = data[(2*datasize-1):datasize];
else
    X{datasize}(t)  = data[(datasize-1):0];
    X{datasize}(t2) = data[(2*datasize-1):datasize];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDTP

Load unprivileged pair of registers

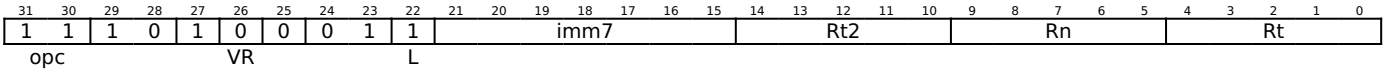
This instruction calculates an address from a base register value and an immediate offset, loads two 64-bit doublewords from memory, and writes them to two registers.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.
For information about addressing modes, see *Load/Store addressing modes*.
It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index

(FEAT_LSUI)



Encoding

```
LDTP <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

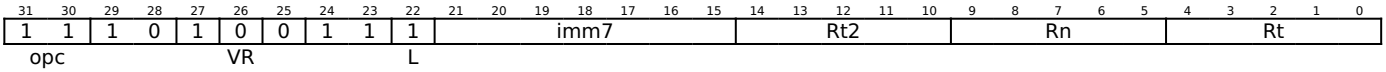
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

var wback : boolean = TRUE;
let postindex : boolean = TRUE;
```

Pre-index

(FEAT_LSUI)



Encoding

```
LDTP <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

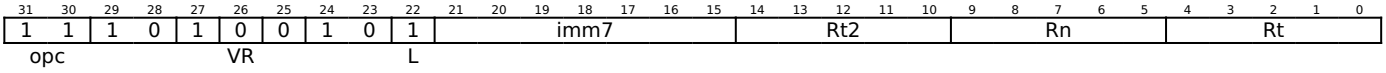
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

var wback : boolean = TRUE;
let postindex : boolean = FALSE;
```

Signed offset

(FEAT_LSUI)



Encoding

```
LDTP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

var wback : boolean = FALSE;
let postindex : boolean = FALSE;
```

LDTP has the same CONSTRAINED UNPREDICTABLE behavior as LDP. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDP*.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> For the "Post-index" and "Pre-index" variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8.

For the "Signed offset" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Shared Decode

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let scale : integer{} = 2 + UInt(opc[1]);

LDTR

Load register (unprivileged)

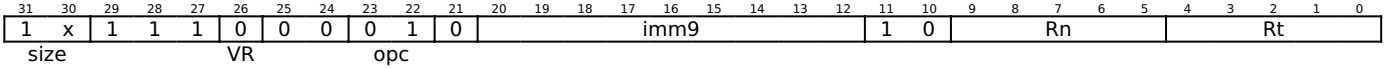
This instruction loads a word or doubleword from memory, and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDTR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDTR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 8 << scale;
let regsize : integer{} = if datasize == 64 then 64 else 32;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDTRB

Load register byte (unprivileged)

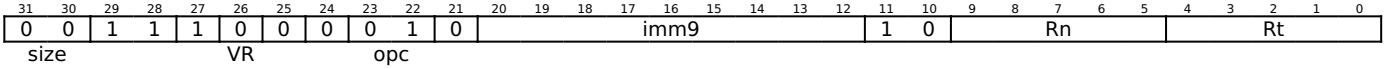
This instruction loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDTRB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 8;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDTRH

Load register halfword (unprivileged)

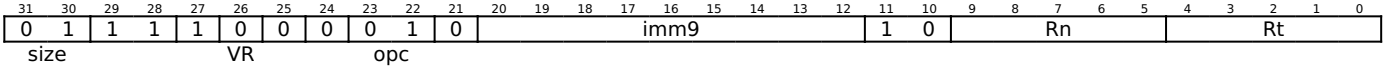
This instruction loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDTRH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 16;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

LDTRSB

Load register signed byte (unprivileged)

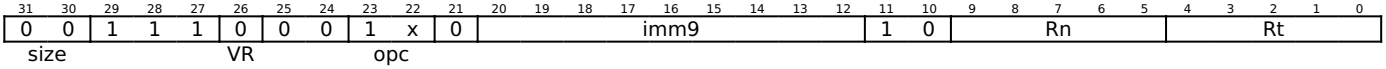
This instruction loads a byte from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDTRSB <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDTRSB <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 8;
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

LDTRSH

Load register signed halfword (unprivileged)

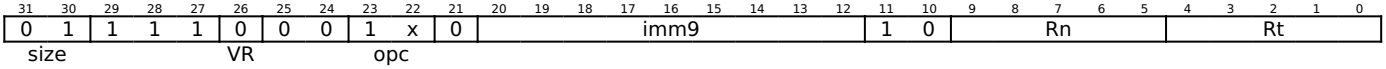
This instruction loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDTRSH <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDTRSH <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 16;
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDTRSW

Load register signed word (unprivileged)

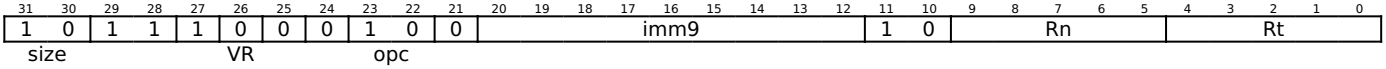
This instruction loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDTRSW <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 32;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{64}(t) = SignExtend{64}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDTSET, LDTSETA, LDTSETAL, LDTSETL

Atomic bit set unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR, or XZR, `LDTSETA` and `LDTSETAL` load from memory with acquire semantics.
- `LDTSETL` and `LDTSETAL` store to memory with release semantics.
- `LDTSET` has neither acquire nor release semantics.

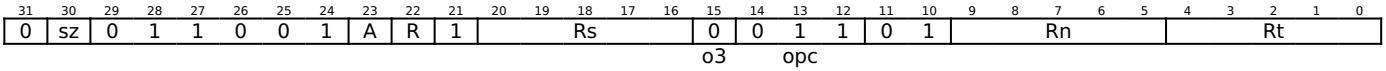
For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.
This instruction is used by the alias STTSET, STTSETL.

Integer

(FEAT_LSUI)



Encoding for the 32-bit no memory ordering variant

Applies when `(sz == 0 && A == 0 && R == 0)`

```
LDTSET <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire variant

Applies when `(sz == 0 && A == 1 && R == 0)`

```
LDTSETA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire-release variant

Applies when `(sz == 0 && A == 1 && R == 1)`

```
LDTSETAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit release variant

Applies when `(sz == 0 && A == 0 && R == 1)`

```
LDTSETL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit no memory ordering variant

Applies when `(sz == 1 && A == 0 && R == 0)`

```
LDTSET <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire variant

Applies when `(sz == 1 && A == 1 && R == 0)`

```
LDTSETA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire-release variant

Applies when `(sz == 1 && A == 1 && R == 1)`

```
LDTSETAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit release variant

Applies when `(sz == 1 && A == 0 && R == 1)`

```
LDTSETL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 32 << UInt(sz);
let regsize : integer{} = if datasize == 64 then 64 else 32;

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Alias Conditions

Alias	Is preferred when
STTSET, STTSETL	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_ORR, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(datasize) = ARBITRARY : bits(datasize); // Irrelevant when not executing CAS
let value : bits(datasize) = X{datasize}(s);
let data : bits(datasize) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{regsize}(t) = ZeroExtend{regsize}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDTXR

Load unprivileged exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

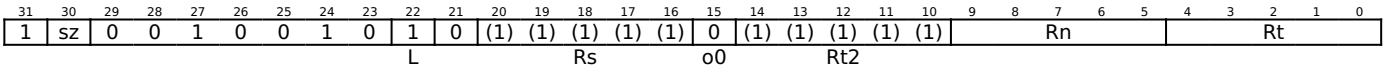
Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `LDTXR` is equivalent to `LDXR`.

For information about addressing modes, see *Load/Store addressing modes*.

No offset

(FEAT_LSUI)



Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
LDTXR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
LDTXR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let regsize : integer{} = if elsize == 64 then 64 else 32;
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem{elsize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH

Atomic unsigned maximum on halfword

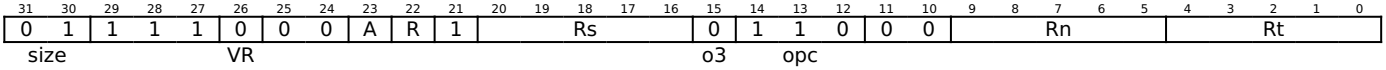
This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDUMAXAH` and `LDUMAXALH` load from memory with acquire semantics.
- `LDUMAXLH` and `LDUMAXALH` store to memory with release semantics.
- `LDUMAXH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STUMAXH, STUMAXLH.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDUMAXH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDUMAXAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDUMAXALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDUMAXLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STUMAXH, STUMAXLH	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;

LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB

Atomic unsigned minimum on byte

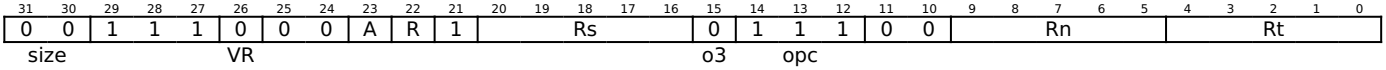
This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDUMINAB` and `LDUMINALB` load from memory with acquire semantics.
- `LDUMINLB` and `LDUMINALB` store to memory with release semantics.
- `LDUMINB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STUMINB, STUMINLB.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDUMINB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDUMINAB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDUMINALB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDUMINLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STUMINB, STUMINLB	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_UMIN, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(8) = ARBITRARY : bits(8); // Irrelevant when not executing CAS
let value : bits(8) = X{8}(s);
let data : bits(8) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{32}(t) = ZeroExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH

Atomic unsigned minimum on halfword

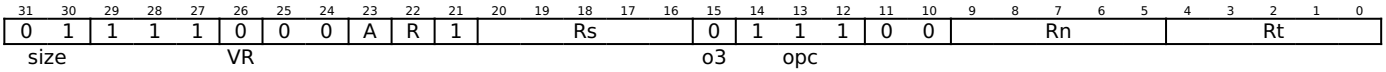
This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDUMINAH` and `LDUMINALH` load from memory with acquire semantics.
- `LDUMINLH` and `LDUMINALH` store to memory with release semantics.
- `LDUMINH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.
This instruction is used by the alias STUMINH, STUMINLH.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(A == 0 && R == 0)`

```
LDUMINH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant

Applies when `(A == 1 && R == 0)`

```
LDUMINAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant

Applies when `(A == 1 && R == 1)`

```
LDUMINALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant

Applies when `(A == 0 && R == 1)`

```
LDUMINLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
STUMINH, STUMINLH	`A == '0' && Rt == '11111'`

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_UMIN, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let comparevalue : bits(16) = ARBITRARY : bits(16); // Irrelevant when not executing CAS
let value : bits(16) = X{16}(s);
let data : bits(16) = MemAtomic{}(address, comparevalue, value, accdesc);

if t != 31 then
    X{32}(t) = ZeroExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

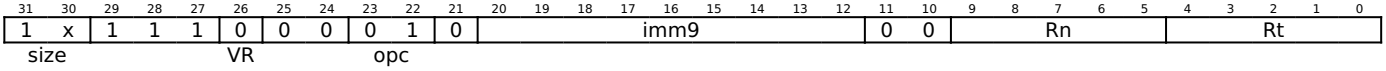
LDUR

Load register (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a 32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDUR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 8 << scale;
let regsize : integer{} = if datasize == 64 then 64 else 32;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

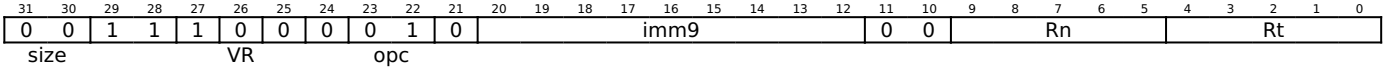
LDURB

Load register byte (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a byte from memory, zero-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 8;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

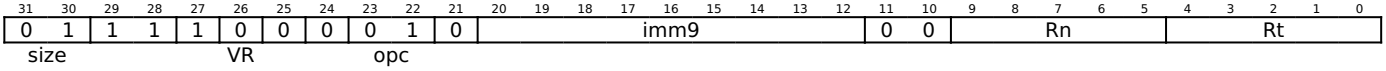
LDURH

Load register halfword (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a halfword from memory, zero-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 16;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

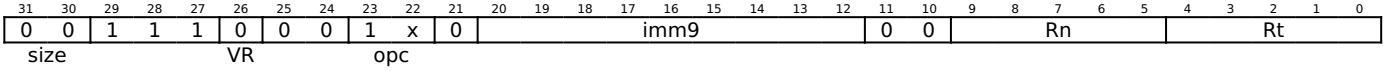
LDURSB

Load register signed byte (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed byte from memory, sign-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDURSB <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDURSB <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 8;
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

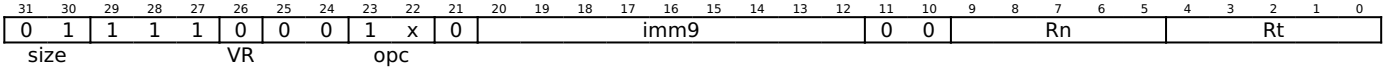
LDURSH

Load register signed halfword (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed halfword from memory, sign-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(opc == 11)`

```
LDURSH <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
LDURSH <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 16;
let regsize : integer{} = 64 >> UInt(opc[0]);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{regsize}(t) = SignExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

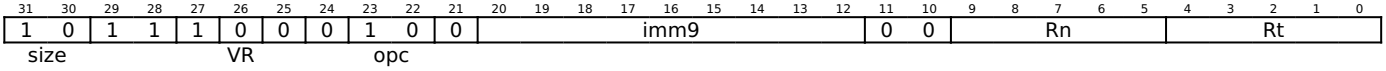
LDURSW

Load register signed word (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDURSW <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 32;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

let data : bits(datasize) = Mem{datasize}(address, accdesc);
X{64}(t) = SignExtend{64}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

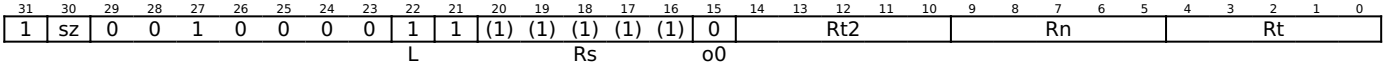
LDXP

Load exclusive pair of registers

This instruction derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
LDXP <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
LDXP <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let datasize : integer{} = elsize * 2;
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // result is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs* and *LDXP*.

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Operation

```
var address : bits(64);
var data : bits(datasize);

let dbytes : integer{} = datasize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
// When elsize is 32, the access is single-copy atomic
let ispair : boolean = elsize == 64;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, ispair, t, t2);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem{datasize}(address, accdesc);
if rt_unknown then
    // ConstrainedUNPREDICTABLE case
    X{datasize}(t)  = ARBITRARY : bits(datasize);        // In this case t = t2
elsif BigEndian(accdesc.acctype) then
    X{elsize}(t)  = data[elsize +: elsize];
    X{elsize}(t2) = data[0 +: elsize];
else
    X{elsize}(t)  = data[0 +: elsize];
    X{elsize}(t2) = data[elsize +: elsize];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

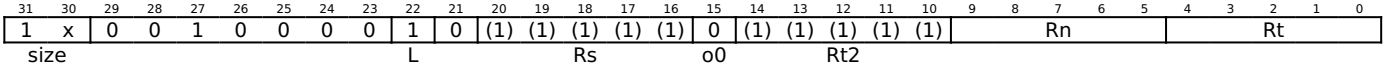
LDXR

Load exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
LDXR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
LDXR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 8 << UInt(size);
let regsize : integer{} = if elsize == 64 then 64 else 32;
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem{elsize}(address, accdesc);
X{regsize}(t) = ZeroExtend{regsize}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

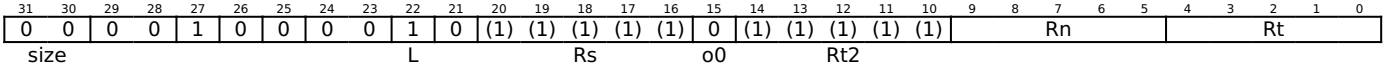
LDXRB

Load exclusive register byte

This instruction derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDXRB <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
var data : bits(8);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, 1, accdesc);

data = Mem{8}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

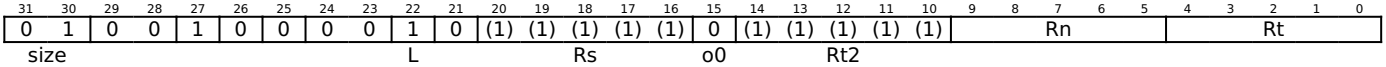
LDXRH

Load exclusive register halfword

This instruction derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
LDXRH <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
var data : bits(16);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_LOAD, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

AArch64_SetExclusiveMonitors(address, 2, accdesc);

data = Mem{16}(address, accdesc);
X{32}(t) = ZeroExtend{32}(data);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

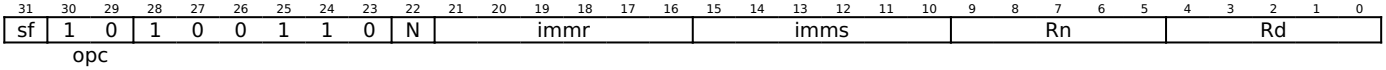
LSL (immediate)

Logical shift left (immediate)

This instruction shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms != 011111)`

```
LSL <Wd>, <Wn>, #<shift>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #(-<shift> MOD 32), #(31-<shift>)
```

and is the preferred disassembly when `UInt(imms) + 1 == UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1 && imms != 111111)`

```
LSL <Xd>, <Xn>, #<shift>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #(-<shift> MOD 64), #(63-<shift>)
```

and is the preferred disassembly when `UInt(imms) + 1 == UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift>	For the "32-bit" variant: is the shift amount, in the range 0 to 31. For the "64-bit" variant: is the shift amount, in the range 0 to 63.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

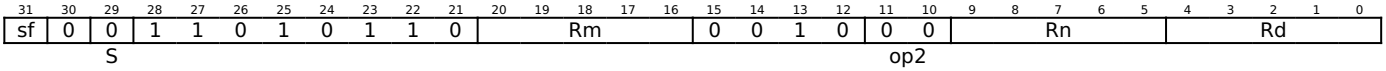
LSL (register)

Logical shift left (register)

This instruction shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is left-shifted.

This is an alias of LSLV. This means:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
LSL <Wd>, <Wn>, <Wm>
```

is equivalent to

```
LSLV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
LSL <Xd>, <Xn>, <Xm>
```

is equivalent to

```
LSLV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of LSLV gives the operational pseudocode for this instruction.

Operational Information

The description of LSLV gives the operational information for this instruction.

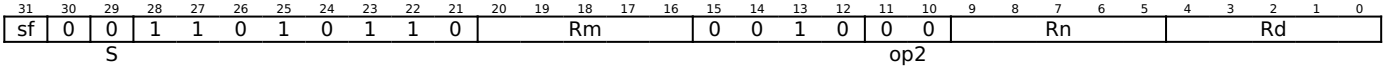
LSLV

Logical shift left variable

This instruction shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
LSLV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
LSLV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(op2);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
let operand2 : bits(datasize) = X{datasize}(m);

X{datasize}(d) = ShiftReg{datasize}(n, shift_type, UInt(operand2) MOD datasize);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

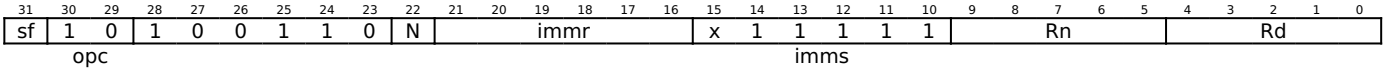
LSR (immediate)

Logical shift right (immediate)

This instruction shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms == 011111)`

```
LSR <Wd>, <Wn>, #<shift>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #<shift>, #31
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1 && imms == 111111)`

```
LSR <Xd>, <Xn>, #<shift>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #<shift>, #63
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

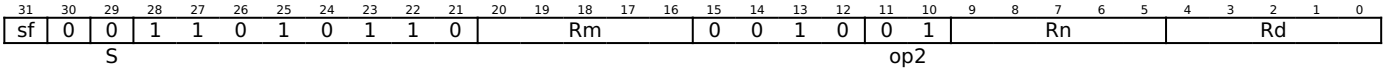
LSR (register)

Logical shift right (register)

This instruction shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of LSRV. This means:

- The encodings in this description are named to match the encodings of LSRV.
- The description of LSRV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
LSR <Wd>, <Wn>, <Wm>
```

is equivalent to

```
LSRV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
LSR <Xd>, <Xn>, <Xm>
```

is equivalent to

```
LSRV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of LSRV gives the operational pseudocode for this instruction.

Operational Information

The description of LSRV gives the operational information for this instruction.

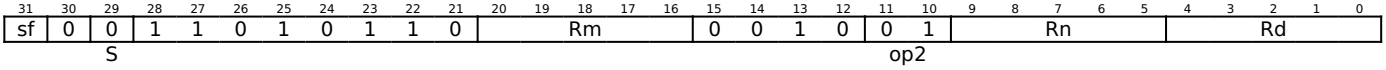
LSRV

Logical shift right variable

This instruction shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This instruction is used by the alias LSR (register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
LSRV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
LSRV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(op2);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
let operand2 : bits(datasize) = X{datasize}(m);

X{datasize}(d) = ShiftReg{datasize}(n, shift_type, UInt(operand2) MOD datasize);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

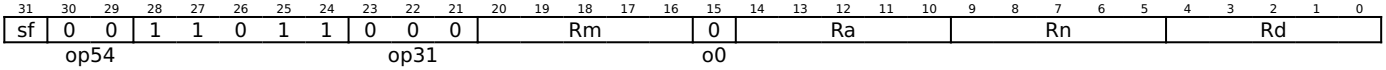
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

MADD

Multiply-add

This instruction multiplies two register values, adds a third register value, and writes the result to the destination register.
This instruction is used by the alias MUL.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MADD <Wd>, <Wn>, <Wm>, <Wa>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MADD <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Wa>	Is the 32-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
MUL	`Ra == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let operand3 : bits(datasize) = X{datasize}(a);

let result : integer = UInt(operand3) + UInt(operand1) * UInt(operand2);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

MADDPT

Multiply-add checked pointer

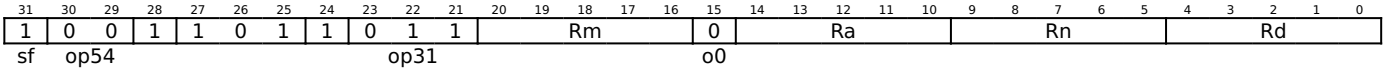
This instruction multiplies two register values, adds a third register value, and writes the result to the destination register. The intermediate product is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

If the intermediate product cannot be correctly represented as a 64-bit two's complement value, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)



Encoding

```
MADDPT <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CPA) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

```
let operand1 : bits(64) = X{64}(n);
let operand2 : bits(64) = X{64}(m);
let operand3 : bits(64) = X{64}(a);

var result : bits(64);

let product : integer = SInt(operand1) * SInt(operand2);

// Signed and unsigned twos complement arithmetic are equivalent if only a
// fixed number of bits are considered.
result = operand3 + product[63:0];

let overflow : boolean = (product != SInt(product[63:0]));
result = PointerMultiplyAddCheck(result, operand3, overflow);

X{64}(d) = result;
```

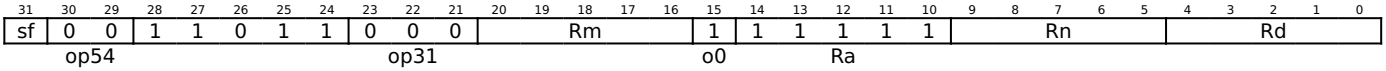
MNEG

Multiply-negate

This instruction multiplies two register values, negates the product, and writes the result to the destination register.

This is an alias of MSUB. This means:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MNEG <Wd>, <Wn>, <Wm>
```

is equivalent to

```
MSUB <Wd>, <Wn>, <Wm>, WZR
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MNEG <Xd>, <Xn>, <Xm>
```

is equivalent to

```
MSUB <Xd>, <Xn>, <Xm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MSUB gives the operational pseudocode for this instruction.

Operational Information

The description of MSUB gives the operational information for this instruction.

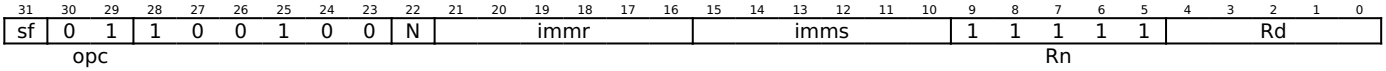
MOV (bitmask immediate)

Move bitmask immediate value

This instruction writes a bitmask immediate value to a register.

This is an alias of ORR (immediate). This means:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
MOV <Wd|WSP>, #<imm>
```

is equivalent to

```
ORR <Wd|WSP>, WZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV <Xd|SP>, #<imm>
```

is equivalent to

```
ORR <Xd|SP>, XZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

Assembler Symbols

<Wd|WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<imm>	For the "32-bit" variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN. For the "64-bit" variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.
<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ORR (immediate) gives the operational information for this instruction.

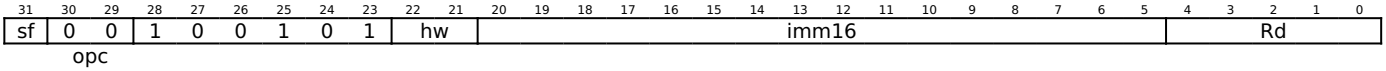
MOV (inverted wide immediate)

Move inverted wide immediate value

This instruction moves an inverted 16-bit immediate value to a register.

This is an alias of MOVN. This means:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOV <Wd>, #<imm>
```

is equivalent to

```
MOVN <Wd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00') && !IsOnes(imm16)`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV <Xd>, #<imm>
```

is equivalent to

```
MOVN <Xd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	For the "32-bit" variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xFFFF0000 and 0x0000FFFF. For the "64-bit" variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of MOVN gives the operational pseudocode for this instruction.

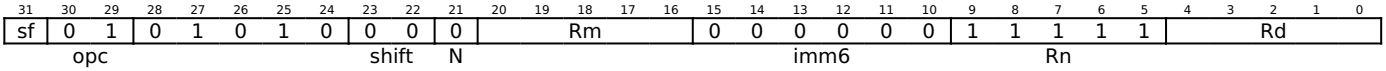
MOV (register)

Move register value

This instruction copies the value in a source register to the destination register.

This is an alias of ORR (shifted register). This means:

- The encodings in this description are named to match the encodings of ORR (shifted register).
- The description of ORR (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MOV <Wd>, <Wm>
```

is equivalent to

```
ORR <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV <Xd>, <Xm>
```

is equivalent to

```
ORR <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wm>	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xm>	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of ORR (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ORR (shifted register) gives the operational information for this instruction.

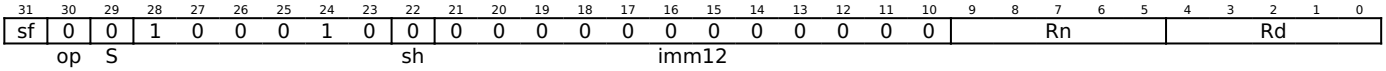
MOV (to/from SP)

Move register value to or from SP

This instruction copies the value of a register to or from the stack pointer.

This is an alias of ADD (immediate). This means:

- The encodings in this description are named to match the encodings of ADD (immediate).
- The description of ADD (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MOV <Wd|WSP>, <Wn|WSP>
```

is equivalent to

```
ADD <Wd|WSP>, <Wn|WSP>, #0
```

and is the preferred disassembly when `Rd == '11111' || Rn == '11111'`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV <Xd|SP>, <Xn|SP>
```

is equivalent to

```
ADD <Xd|SP>, <Xn|SP>, #0
```

and is the preferred disassembly when `Rd == '11111' || Rn == '11111'`.

Assembler Symbols

<Wd|WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn|WSP>	Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of ADD (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ADD (immediate) gives the operational information for this instruction.

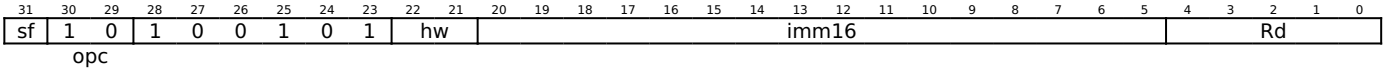
MOV (wide immediate)

Move wide immediate value

This instruction moves a 16-bit immediate value to a register.

This is an alias of MOVZ. This means:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOV <Wd>, #<imm>
```

is equivalent to

```
MOVZ <Wd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOV <Xd>, #<imm>
```

is equivalent to

```
MOVZ <Xd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	For the "32-bit" variant: is a 32-bit immediate which can be encoded in "imm16:hw". For the "64-bit" variant: is a 64-bit immediate which can be encoded in "imm16:hw".
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of MOVZ gives the operational pseudocode for this instruction.

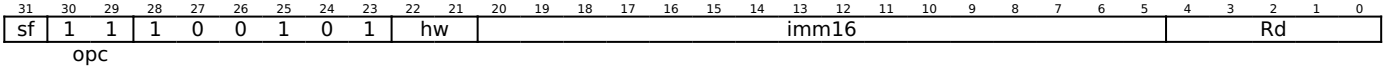
MOVK

Move wide with keep

This instruction moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.



Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOVK <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOVK <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw[1] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let datasize : integer{} = 32 << UInt(sf);
let imm : bits(16) = imm16;
let pos : integer{} = UInt(hw) << 4;
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift>	For the "32-bit" variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the "64-bit" variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32, or 48, encoded in the "hw" field as <shift>/16.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

```
var result : bits(datasize) = X{datasize}(d);

result[pos+15:pos] = imm;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

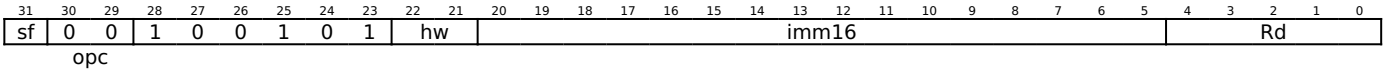
MOVN

Move wide with NOT

This instruction moves the inverse of an optionally-shifted 16-bit immediate value to a register.
This instruction is used by the alias MOV (inverted wide immediate).



Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOVN <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOVN <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw[1] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let datasize : integer{} = 32 << UInt(sf);
let imm : bits(16) = imm16;
let pos : integer{} = UInt(hw) << 4;
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift>	For the "32-bit" variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the "64-bit" variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32, or 48, encoded in the "hw" field as <shift>/16.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Alias Conditions

Alias	Of variant	Is preferred when
MOV (inverted wide immediate)	32-bit	`!(IsZero(imm16) && hw != '00') && !IsOnes(imm16)`
MOV (inverted wide immediate)	64-bit	`!(IsZero(imm16) && hw != '00')`

Operation

```
var result : bits(datasize) = Zeros{};

result[pos+15:pos] = imm;

X{datasize}(d) = NOT result;
```

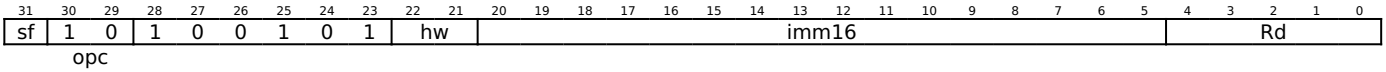
MOVZ

Move wide with zero

This instruction moves an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (wide immediate).



Encoding for the 32-bit variant

Applies when `(sf == 0 && hw == 0x)`

```
MOVZ <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MOVZ <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw[1] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let datasize : integer{} = 32 << UInt(sf);
let imm : bits(16) = imm16;
let pos : integer{} = UInt(hw) << 4;
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift>	For the "32-bit" variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the "64-bit" variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32, or 48, encoded in the "hw" field as <shift>/16.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Alias Conditions

Alias	Is preferred when
MOV (wide immediate)	`!(IsZero(imm16) && hw != '00')`

Operation

```
var result : bits(datasize) = Zeros{};

result[pos+15:pos] = imm;

X{datasize}(d) = result;
```

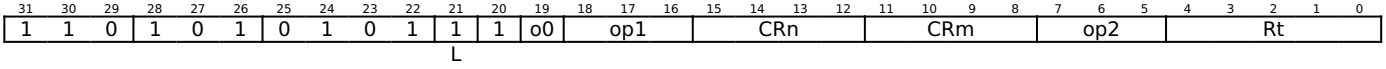
MRRS

Move System register to two adjacent general-purpose registers

This instruction allows the PE to read an AArch64 128-bit System register into two adjacent 64-bit general-purpose registers.

System

(FEAT_SYSREG128)



Encoding

```
MRRS <Xt>, <Xt+1>, (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>)
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SYSREG128) then EndOfDecode(Decode_UNDEF); end;
if Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;

let t : integer       = UInt(Rt);
let t2 : integer      = UInt(Rt+1);
let sys_op0 : bits(2) = '1' :: o0;
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<Xt>	Is the 64-bit name of the first general-purpose destination register, encoded in the "Rt" field.
<Xt+1>	Is the 64-bit name of the second general-purpose destination register, encoded as "Rt" +1.
<systemreg>	Is a System register name, encoded in "o0:op1:CRn:CRm:op2".
<op0>	Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Operation

```
AArch64_SysRegRead128(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, t2);
```

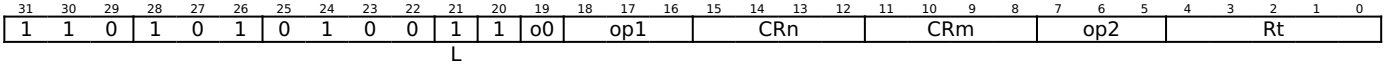
MRS

Move System register to general-purpose register

This instruction allows the PE to read an AArch64 System register into a general-purpose register.



Encoding

```
MRS <Xt>, (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>)
```

Decode for this encoding

```
let t : integer       = UInt(Rt);
let sys_op0 : bits(2) = '1' :: o0;
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

<systemreg> Is a System register name, encoded in "o0:op1:CRn:CRm:op2". The System register names are defined in *AArch64 System Register Descriptions*.

<op0> Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Operation

```
AArch64_SysRegRead(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

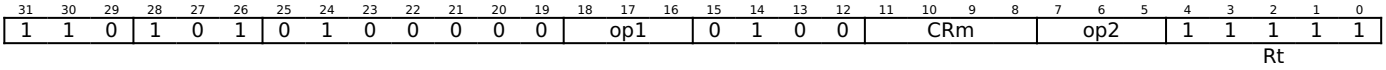
MSR (immediate)

Move immediate value to special register

This instruction moves an immediate value to selected bits of the PSTATE. For more information, see *Process state, PSTATE*.
The bits that can be written by this instruction are:

- PSTATE.D, PSTATE.A, PSTATE.I, PSTATE.F, and PSTATE.SP.
- If *FEAT_SSBS* is implemented, PSTATE.SSBS.
- If *FEAT_PAN* is implemented, PSTATE.PAN.
- If *FEAT_UAO* is implemented, PSTATE.UAO.
- If *FEAT_DIT* is implemented, PSTATE.DIT.
- If *FEAT_MTE* is implemented, PSTATE.TCO.
- If *FEAT_NMI* is implemented, PSTATE.ALLINT.
- If *FEAT_SME* is implemented, PSTATE.SM and PSTATE.ZA.
- If *FEAT_EBEP*, *FEAT_SPE_EXC*, or *FEAT_TRBE_EXC* is implemented, PSTATE.PM.

If *FEAT_MTE* is implemented and *FEAT_MTE2* is not implemented, it is IMPLEMENTATION DEFINED whether writes to PSTATE.TCO by this instruction are ignored.
This instruction is used by the aliases SMSTART, and SMSTOP.



Encoding

Applies when `(!(op1 == 000 && op2 IN {00x, 010}))`

```
MSR <pstatefield>, #<imm>
```

Decode for this encoding

```
if op1 == '000' && op2 == '000' then See("CFINV"); end;
if op1 == '000' && op2 == '001' then See("XAFLAG"); end;
if op1 == '000' && op2 == '010' then See("AXFLAG"); end;

var min_EL : bits(2);
var need_secure : boolean = FALSE;

case op1 of
    when '00x' =>
        min_EL = EL1;
    when '010' =>
        min_EL = EL1;
    when '011' =>
        min_EL = EL0;
    when '100' =>
        min_EL = EL2;
    when '101' =>
        if !IsFeatureImplemented(FEAT_VHE) then EndOfDecode(Decode_UNDEF); end;
        min_EL = EL2;
    when '110' =>
        min_EL = EL3;
    when '111' =>
        min_EL = EL1;
        need_secure = TRUE;
end;

let operand : bits(4) = CRm;
var field : PSTATEField;
case op1::op2 of
    when '000 011' =>

    when '001 000' =>
        case CRm of
            when '000x' =>
                if !IsFeatureImplemented(FEAT_NMI) then EndOfDecode(Decode_UNDEF); end;
                field = PSTATEField_ALLINT;
            when '001x' =>
                if (!IsFeatureImplemented(FEAT_EBEP) &&
                      !IsFeatureImplemented(FEAT_SPE_EXC) &&
                      !IsFeatureImplemented(FEAT_TRBE_EXC)) then EndOfDecode(Decode_UNDEF); end;
                field = PSTATEField_PM;
            otherwise =>
                EndOfDecode(Decode_UNDEF);
        end;
    when '011 010' =>
        if !IsFeatureImplemented(FEAT_DIT) then EndOfDecode(Decode_UNDEF); end;
        field = PSTATEField_DIT;
    when '011 011' =>
        case CRm of
            when '001x' =>
                if !IsFeatureImplemented(FEAT_SME) then EndOfDecode(Decode_UNDEF); end;
                field = PSTATEField_SVCRSM;
            when '010x' =>
                if !IsFeatureImplemented(FEAT_SME) then EndOfDecode(Decode_UNDEF); end;
                field = PSTATEField_SVCRZA;
            when '011x' =>
                if !IsFeatureImplemented(FEAT_SME) then EndOfDecode(Decode_UNDEF); end;
                field = PSTATEField_SVCRSMZA;
            otherwise =>
                EndOfDecode(Decode_UNDEF);
        end;
    when '011 100' =>
        if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
        field = PSTATEField_TCO;
    when '011 110' => field = PSTATEField_DAIFSet;
    when '011 111' => field = PSTATEField_DAIFClr;
    when '011 001' =>
        if !IsFeatureImplemented(FEAT_SSBS) then EndOfDecode(Decode_UNDEF); end;
        field = PSTATEField_SSBS;
    otherwise =>      EndOfDecode(Decode_UNDEF);
end;
```

Assembler Symbols

<pstatefield> Is a PSTATE field name. For the MSR instruction, this is encoded in “(CRm :: op1 :: op2)”:

CRm	op1	op2	<pstatefield>	Architectural Feature
xxxx	000	011	UAO	FEAT_UAO
xxxx	000	100	PAN	FEAT_PAN
xxxx	000	101	SPSel	-
xxxx	000	11x	RESERVED	-
000x	001	000	ALLINT	FEAT_NMI
xxxx	001	001	RESERVED	-
xxxx	001	01x	RESERVED	-
xxxx	001	1xx	RESERVED	-
xxxx	010	xxx	RESERVED	-
xxxx	011	000	RESERVED	-
xxxx	011	001	SSBS	FEAT_SSBS
xxxx	011	010	DIT	FEAT_DIT
000x	011	011	RESERVED	-
xxxx	011	100	TCO	FEAT_MTE
xxxx	011	101	RESERVED	-
xxxx	011	110	DAIFSet	-
xxxx	011	111	DAIFClr	-
xxxx	1xx	xxx	RESERVED	-
001x	001	000	PM	FEAT_EBEP || FEAT_SPE_EXC || FEAT_TRBE_EXC
001x	011	011	SVCRSM	FEAT_SME
01xx	001	000	RESERVED	-
010x	011	011	SVCRZA	FEAT_SME
011x	011	011	SVCRSMZA	FEAT_SME
1xxx	001	000	RESERVED	-
1xxx	011	011	RESERVED	-

For the SMSTART and SMSTOP aliases, this is encoded in "CRm<2:1>", where 0b01 specifies SVCRSM, 0b10 specifies SVCRZA, and 0b11 specifies SVCRSMZA.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field. Restricted to the range 0 to 1, encoded in "CRm<0>", when <pstatefield> is ALLINT, PM, SVCRSM, SVCRSMZA, or SVCRZA.

Alias Conditions

Alias	Is preferred when
SMSTART	`op1 == '011' && CRm IN {'0xx1'} && op2 == '011'`
SMSTOP	`op1 == '011' && CRm IN {'0xx0'} && op2 == '011'`

Operation

```
if UInt(PSTATE.EL) < UInt(min_EL) then Undefined(); end;
if need_secure && CurrentSecurityState() != SS_Secure then Undefined(); end;

case field of
    when PSTATEField_SSBS =>
        PSTATE.SSBS = operand[0];

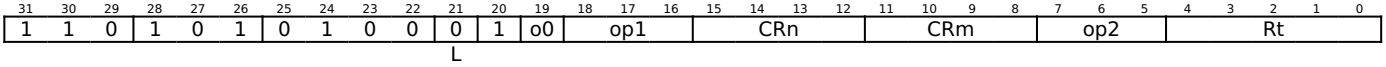
MSR (register)

Move general-purpose register to System register

This instruction allows the PE to write an AArch64 System register from a general-purpose register.



Encoding

```
MSR (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>), <Xt>
```

Decode for this encoding

```
let t : integer       = UInt(Rt);
let sys_op0 : bits(2) = '1' :: o0;
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<systemreg> Is a System register name, encoded in "o0:op1:CRn:CRm:op2". The System register names are defined in *AArch64 System Register Descriptions*.

<op0> Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

```
AArch64_SysRegWrite(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

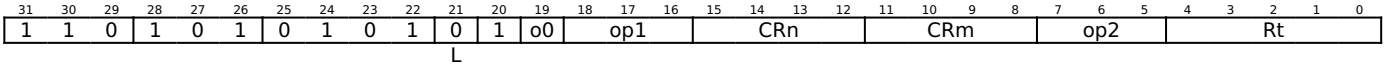
MSRR

Move two adjacent general-purpose registers to System register

This instruction allows the PE to write an AArch64 128-bit System register from two adjacent 64-bit general-purpose registers.

System

(FEAT_SYSREG128)



Encoding

```
MSRR (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>), <Xt>, <Xt+1>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SYSREG128) then EndOfDecode(Decode_UNDEF); end;
if Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;

let t : integer       = UInt(Rt);
let t2 : integer      = UInt(Rt+1);
let sys_op0 : bits(2) = '1' :: o0;
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<systemreg> Is a System register name, encoded in "o0:op1:CRn:CRm:op2".

<op0> Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the first general-purpose source register, encoded in the "Rt" field.

<Xt+1> Is the 64-bit name of the second general-purpose source register, encoded as "Rt" +1.

Operation

```
AArch64_SysRegWrite128(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, t2);
```

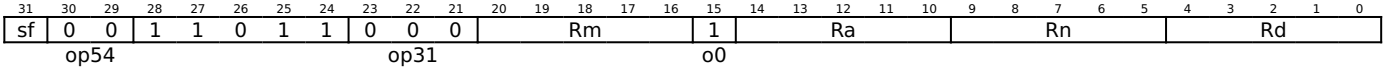
MSUB

Multiply-subtract

This instruction multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register. This instruction is used by the alias MNEG.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MSUB <Wd>, <Wn>, <Wm>, <Wa>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MSUB <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Wa>	Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
MNEG	`Ra == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let operand3 : bits(datasize) = X{datasize}(a);

let result : integer = UInt(operand3) - UInt(operand1) * UInt(operand2);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

MSUBPT

Multiply-subtract checked pointer

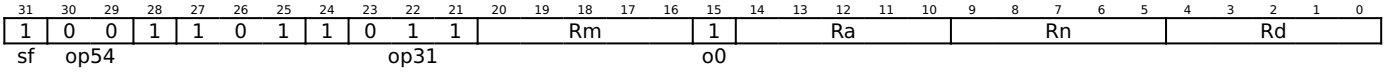
This instruction multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register. The intermediate product is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

If the intermediate product cannot be correctly represented as a 64-bit two's complement value, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)



Encoding

```
MSUBPT <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CPA) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```
let operand1 : bits(64) = X{64}(n);
let operand2 : bits(64) = X{64}(m);
let operand3 : bits(64) = X{64}(a);

var result : bits(64);

let product : integer = SInt(operand1) * SInt(operand2);

// Signed and unsigned twos complement arithmetic are equivalent if only a
// fixed number of bits are considered.
result = operand3 - product[63:0];

let overflow : boolean = (product != SInt(product[63:0]));
result = PointerMultiplyAddCheck(result, operand3, overflow);

X{64}(d) = result;
```

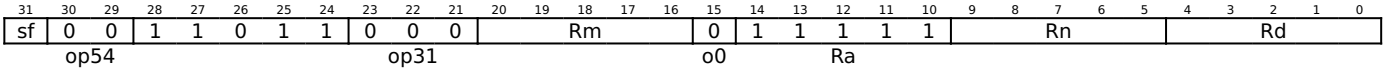
MUL

Multiply

This instruction multiplies two register values and writes the result to the destination register.

This is an alias of MADD. This means:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MUL <Wd>, <Wn>, <Wm>
```

is equivalent to

```
MADD <Wd>, <Wn>, <Wm>, WZR
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MUL <Xd>, <Xn>, <Xm>
```

is equivalent to

```
MADD <Xd>, <Xn>, <Xm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MADD gives the operational pseudocode for this instruction.

Operational Information

The description of MADD gives the operational information for this instruction.

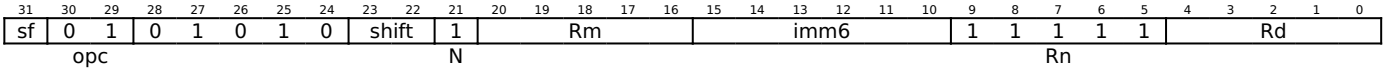
MVN

Bitwise NOT

This instruction writes the bitwise inverse of a register value to the destination register.

This is an alias of ORN (shifted register). This means:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
MVN <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
MVN <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wm> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of ORN (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ORN (shifted register) gives the operational information for this instruction.

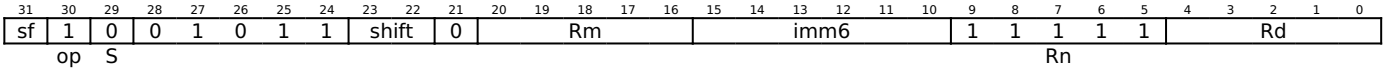
NEG (shifted register)

Negate (shifted register)

This instruction negates an optionally-shifted register value, and writes the result to the destination register.

This is an alias of SUB (shifted register). This means:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
NEG <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUB <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
NEG <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUB <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wm> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of SUB (shifted register) gives the operational information for this instruction.

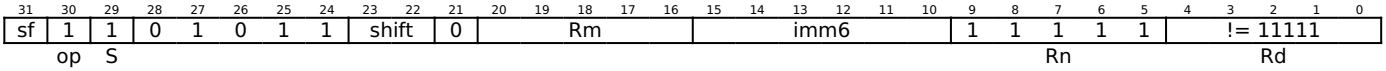
NEGS

Negate, setting flags

This instruction negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
NEGS <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
NEGS <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wm> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of SUBS (shifted register) gives the operational information for this instruction.

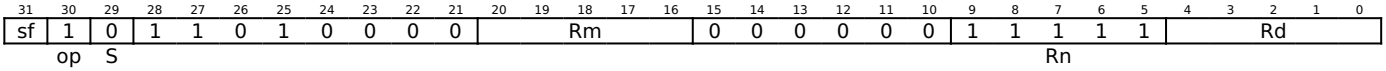
NGC

Negate with carry

This instruction negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This is an alias of SBC. This means:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
NGC <Wd>, <Wm>
```

is equivalent to

```
SBC <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
NGC <Xd>, <Xm>
```

is equivalent to

```
SBC <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wm>	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xm>	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBC gives the operational pseudocode for this instruction.

Operational Information

The description of SBC gives the operational information for this instruction.

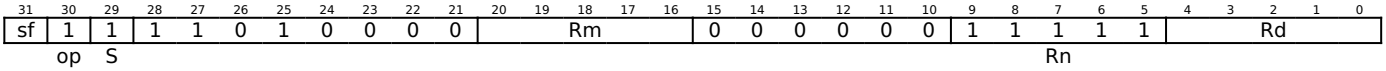
NGCS

Negate with carry, setting flags

This instruction negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SBCS. This means:

- The encodings in this description are named to match the encodings of SBCS.
- The description of SBCS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
NGCS <Wd>, <Wm>
```

is equivalent to

```
SBCS <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
NGCS <Xd>, <Xm>
```

is equivalent to

```
SBCS <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wm>	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xm>	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBCS gives the operational pseudocode for this instruction.

Operational Information

The description of SBCS gives the operational information for this instruction.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

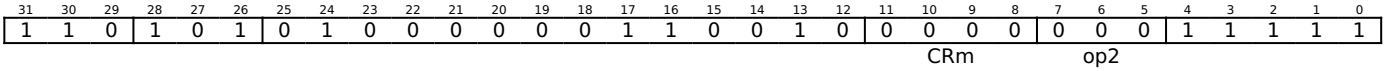
NOP

No operation

This instruction does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a `NOP` instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, `NOP` instructions are not suitable for timing loops.



Encoding

`NOP`

Decode for this encoding

```
// Empty.
```

Operation

```
return; // Do nothing
```

2026-09_rel 2026-09-21 14:22:38

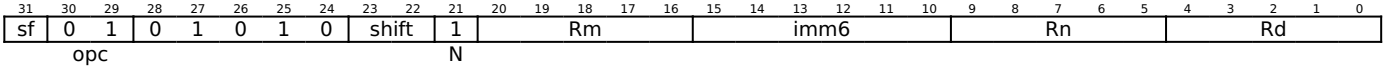
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

ORN (shifted register)

Bitwise OR NOT (shifted register)

This instruction performs a bitwise (inclusive) OR between a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MVN.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ORN <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ORN <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
MVN	`Rn == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 OR NOT operand2;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

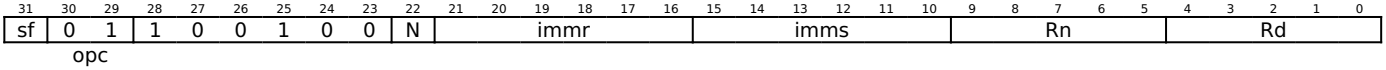
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

ORR (immediate)

Bitwise OR (immediate)

This instruction performs a bitwise (inclusive) OR between a register value and an immediate value, and writes the result to the destination register. This instruction is used by the alias MOV (bitmask immediate).



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
ORR <Wd|WSP>, <Wn>, #<imm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ORR <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
var imm : bits(datasize);
(imm, -) = DecodeBitMasks{datasize}(N, imms, immr, TRUE);
```

Assembler Symbols

<Wd|WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	Is the bitmask immediate. For encoding information, see *Logical (immediate)*.
<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
MOV (bitmask immediate)	`Rn == '11111' && !MoveWidePreferred(sf, N, imms, immr)`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = imm;
let result : bits(datasize) = operand1 OR operand2;

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

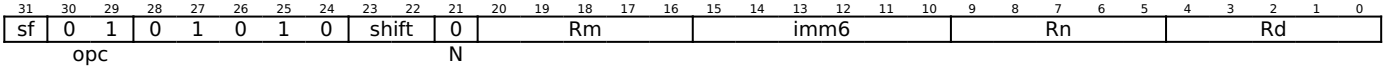
ORR (shifted register)

Bitwise OR (shifted register)

This instruction performs a bitwise (inclusive) OR between a register value and an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MOV (register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ORR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ORR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
MOV (register)	`shift == '00' && imm6 == '000000' && Rn == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = ShiftReg{datasize}(m, shift_type, shift_amount);
let result : bits(datasize) = operand1 OR operand2;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

PACDA, PACDZA

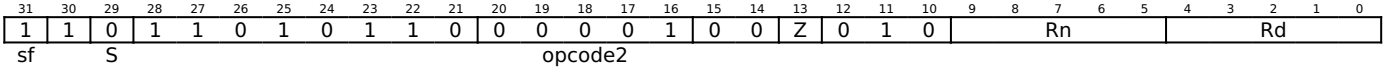
Pointer Authentication Code for data address, using key A

This instruction calculates and inserts a Pointer Authentication Code for a data address, using a modifier and key A.
The address is in the general-purpose register that is specified by <Xd>.
The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDA.
- The value zero, for PACDZA.

Integer

(FEAT_PAuth)



Encoding for the PACDA variant

Applies when `(Z == 0)`

```
PACDA <Xd>, <Xn|SP>
```

Encoding for the PACDZA variant

Applies when `(Z == 1 && Rn == 11111)`

```
PACDZA <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

var source_is_sp : boolean = FALSE;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);

if Z == '0' then // PACDA
    if n == 31 then source_is_sp = TRUE; end;
else // PACDZA
    if n != 31 then EndOfDecode(Decode_UNDEF); end;
end;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X{64}(d) = AddPACDA(X{64}(d), SP{64}());
else
    X{64}(d) = AddPACDA(X{64}(d), X{64}(n));
end;
```

PACDB, PACDZB

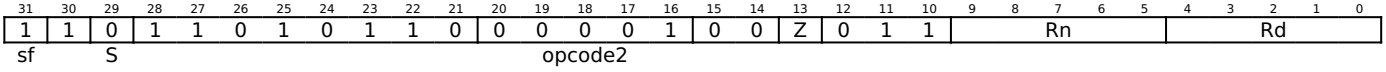
Pointer Authentication Code for data address, using key B

This instruction calculates and inserts a Pointer Authentication Code for a data address, using a modifier and key B.
The address is in the general-purpose register that is specified by <Xd>.
The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDB.
- The value zero, for PACDZB.

Integer

(FEAT_PAuth)



Encoding for the PACDB variant

Applies when `(Z == 0)`

```
PACDB <Xd>, <Xn|SP>
```

Encoding for the PACDZB variant

Applies when `(Z == 1 && Rn == 11111)`

```
PACDZB <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

var source_is_sp : boolean = FALSE;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);

if Z == '0' then // PACDB
    if n == 31 then source_is_sp = TRUE; end;
else // PACDZB
    if n != 31 then EndOfDecode(Decode_UNDEF); end;
end;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X{64}(d) = AddPACDB(X{64}(d), SP{64}());
else
    X{64}(d) = AddPACDB(X{64}(d), X{64}(n));
end;
```

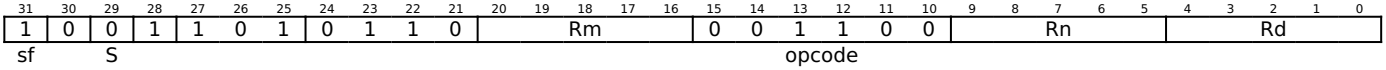
PACGA

Pointer Authentication Code, using generic key

This instruction calculates the Pointer Authentication Code for a 64-bit value in the first source register, using a modifier in the second source register, and the generic key. The calculated Pointer Authentication Code is written to the most significant 32 bits of the destination register, and the least significant 32 bits of the destination register are set to zero.

Integer

(FEAT_PAuth)



Encoding

```
PACGA <Xd>, <Xn>, <Xm|SP>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let source_is_sp : boolean = m == 31;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm|SP>	Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Operation

```
if source_is_sp then
    X{64}(d) = AddPACGA(X{64}(n), SP{64}());
else
    X{64}(d) = AddPACGA(X{64}(n), X{64}(m));
end;
```

PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for instruction address, using key A

This instruction calculates and inserts a Pointer Authentication Code for an instruction address, using a modifier and key A.
The address is:

- In the general-purpose register that is specified by <Xd> for PACIA and PACIZA.
- In X17, for PACIA1716.
- In X30, for PACIASP and PACIAZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIA.
- The value zero, for PACIZA and PACIAZ.
- In X16, for PACIA1716.
- In SP, for PACIASP.

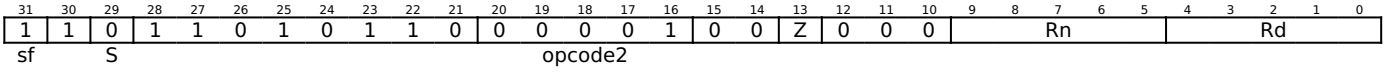
If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then PACIA1716 and PACIASP include a second modifier that is:

- In X15, for PACIA1716.
- The value of PC, for PACIASP.

A PACIASP instruction has an implicit BTI instruction. The implicit BTI instruction of a PACIASP instruction is always compatible with *PSTATE*.BTYPE == 0b01 and *PSTATE*.BTYPE == 0b10. Controls in *SCTLR_ELx* configure whether the implicit BTI instruction of a PACIASP instruction is compatible with *PSTATE*.BTYPE == 0b11. For more information, see *PSTATE.BTYPE*.
It has encodings from 2 classes: Integer and System

Integer

(FEAT_PAuth)



Encoding for the PACIA variant

Applies when (Z == 0)

```
PACIA <Xd>, <Xn|SP>
```

Encoding for the PACIZA variant

Applies when (Z == 1 && Rn == 11111)

```
PACIZA <Xd>
```

Decode for all variants of this encoding

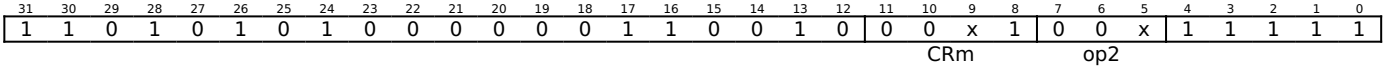
```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
var source_is_sp : boolean = FALSE;
let pacia1716 : boolean = FALSE;

if Z == '0' then // PACIA
    if n == 31 then source_is_sp = TRUE; end;
else // PACIZA
    if n != 31 then EndOfDecode(Decode_UNDEF); end;
end;
```

System

(FEAT_PAuth)



Encoding for the PACIA1716 variant

Applies when (CRm == 0001 && op2 == 000)

```
PACIA1716
```

Encoding for the PACIASP variant

Applies when (CRm == 0011 && op2 == 001)

PACIASP

Encoding for the PACIAZ variant

Applies when (CRm == 0011 && op2 == 000)

PACIAZ

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_NOP); end;

var d : integer;
var n : integer;
var source_is_sp : boolean = FALSE;
var pacia1716 : boolean = FALSE;

case CRm::op2 of
    when '0011 000' => // PACIAZ
        d = 30;
        n = 31;
    when '0011 001' => // PACIASP
        d = 30;
        source_is_sp = TRUE;
        if IsFeatureImplemented(FEAT_BTI) then
            // Check for branch target compatibility between PSTATE.BTYPE
            // and implicit branch target of PACIASP instruction.
            let pacinst : PACInstType = PACIxSP;
            SetBTypeCompatible(BTypeCompatible_PAC(pacinst));
        end;
    when '0001 000' => // PACIA1716
        d = 17;
        n = 16;
        pacia1716 = TRUE;
end;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    if IsFeatureImplemented(FEAT_PAuth_LR) && PSTATE.PACM == '1' then
        X{64}(d) = AddPACIA2(X{64}(d), SP{64}(), PC64());

PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB

Pointer Authentication Code for instruction address, using key B

This instruction calculates and inserts a Pointer Authentication Code for an instruction address, using a modifier and key B.
The address is:

- In the general-purpose register that is specified by <Xd> for PACIB and PACIZB.
- In X17, for PACIB1716.
- In X30, for PACIBSP and PACIBZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIB.
- The value zero, for PACIZB and PACIBZ.
- In X16, for PACIB1716.
- In SP, for PACIBSP.

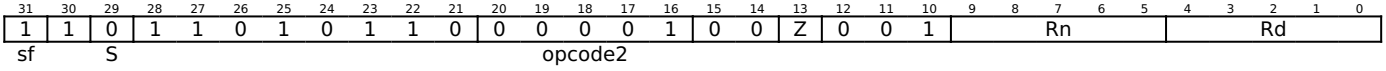
If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then PACIB1716 and PACIBSP include a second modifier that is:

- In X15, for PACIB1716.
- The value of PC, for PACIBSP.

A PACIBSP instruction has an implicit BTI instruction. The implicit BTI instruction of a PACIBSP instruction is always compatible with *PSTATE*.BTYPE == 0b01 and *PSTATE*.BTYPE == 0b10. Controls in *SCTLR_ELx* configure whether the implicit BTI instruction of a PACIBSP instruction is compatible with *PSTATE*.BTYPE == 0b11. For more information, see *PSTATE.BTYPE*.
It has encodings from 2 classes: Integer and System

Integer

(FEAT_PAuth)



Encoding for the PACIB variant

Applies when (Z == 0)

```
PACIB <Xd>, <Xn|SP>

PRFM (immediate)

Prefetch memory (immediate)

This instruction provides a hint to the memory system.

The PRFM IR variant of this instruction signals to the memory system that the thread of execution on the current PE will read a location that might not yet have been updated with the value the thread needs, and that the memory system should optimize for low-latency delivery of that value when the write by the other observer does occur.

The other variants of this instruction signal to the memory system that memory accesses to a location are likely to occur soon. The memory system can respond by taking actions that are expected to speed up the memory access when it does occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

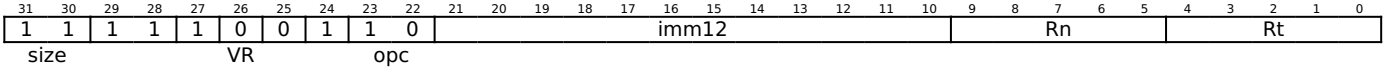
For all variants of this instruction, the address for memory accesses is calculated from a base register value and an immediate offset.

The <prfop> operand specifies the prefetch hint as follows:

- Access type:
  - When FEAT_PCDPHINT is implemented, IR for intent to read on update.
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
  - When FEAT_PRFMSLC is implemented, SLC for system level cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a PRFM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
PRFM (<prfop>|#<imm5>), [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 3);
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = FALSE;
```

11000	IR	FEAT_PCDPHINT

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<pimm> Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_PREFETCH, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);
let supports_ir : boolean = IsFeatureImplemented(FEAT_PCDPHINT);
Prefetch(address, t[4:0], supports_ir);
```

PRFM (literal)

Prefetch memory (literal)

This instruction signals to the memory system that memory accesses to a location are likely to occur soon. The memory system can respond by taking actions that are expected to speed up the memory access when it does occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

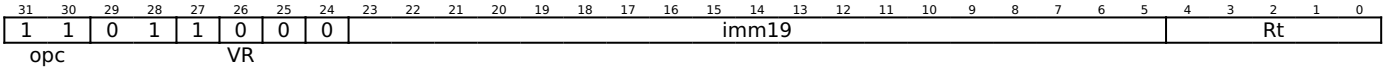
The address for memory accesses is calculated from the PC value and an immediate offset.

The <prfop> operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
  - When FEAT_PRFMSLC is implemented, SLC for system level cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a PRFM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
PRFM (<prfop>|#<imm5>), <label>
```

Decode for this encoding

```
let t : integer = UInt(Rt);

let offset : bits(64) = SignExtend{}(imm19::'00');
```

Assembler Symbols

<prfop> Is the prefetch operation, encoded in “Rt”:

PRFM (register)

Prefetch memory (register)

This instruction signals to the memory system that memory accesses to a location are likely to occur soon. The memory system can respond by taking actions that are expected to speed up the memory access when it does occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

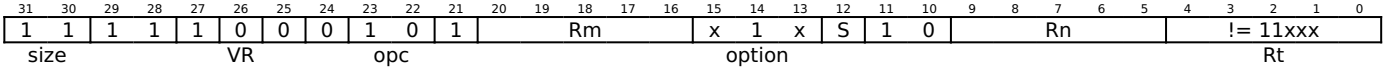
The address for memory accesses is calculated from a base register value and an offset register value. The offset register value can optionally be shifted and extended.

The <prfop> operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
  - When FEAT_PRFMSLC is implemented, SLC for system level cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a PRFM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
PRFM (<prfop>|#<imm5>), [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 3 else 0;
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let m : integer = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = FALSE;
```

Assembler Symbols

<prfop> Is the prefetch operation, encoded in “Rt”:

Rt	<prfop>	Architectural Feature
00000	PLDL1KEEP	-
00001	PLDL1STRM	-
00010	PLDL2KEEP	-
00011	PLDL2STRM	-

10110	PSTSLCKEEP	FEAT_PRFMSLC
10111	PSTSLCSTRM	FEAT_PRFMSLC

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#3

Operation

```
var address : bits(64);

let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_PREFETCH, nontemporal,
                                                  privileged, tagchecked, t);

if n == 31 then
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);
let supports_ir : boolean = FALSE;
Prefetch(address, t[4:0], supports_ir);
```

PRFUM

Prefetch memory (unscaled offset)

This instruction signals to the memory system that memory accesses to a location are likely to occur soon. The memory system can respond by taking actions that are expected to speed up the memory access when it does occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

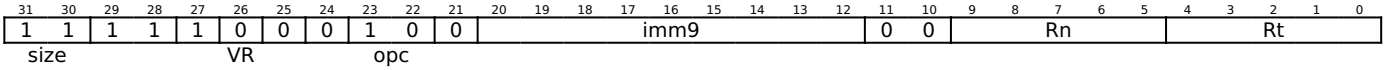
The address for memory accesses is calculated from a base register value and a signed, unscaled immediate offset.

The <prfop> operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
  - When FEAT_PRFMSLC is implemented, SLC for system level cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a PRFUM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
PRFUM (<prfop>|#<imm5>), [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = FALSE;
```

Assembler Symbols

<prfop> Is the prefetch operation, encoded in “Rt”:

PSB

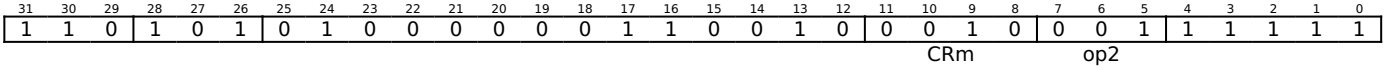
Profiling synchronization barrier

This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. For information about the synchronization behavior when a `DSB` instruction follows a `PSB` instruction in program order, see *Synchronization and Statistical Profiling*.

If *FEAT_SPE* is not implemented, this instruction executes as a `NOP`.

System

(FEAT_SPE)



Encoding

```
PSB CSYNC
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SPE) then EndOfDecode(Decode_NOP); end;
```

Operation

```
CheckPSBTrap();

ProfilingSynchronizationBarrier();
```

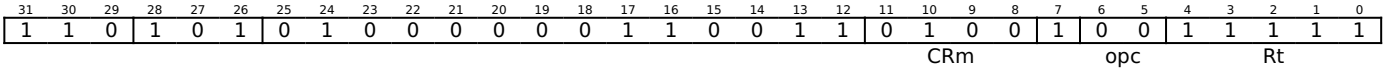
PSSBB

Physical speculative store bypass barrier

This instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions. For more information and details of the semantics, see *Physical Speculative Store Bypass Barrier (PSSBB)*.

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

PSSBB

is equivalent to

```
DSB #4
```

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.

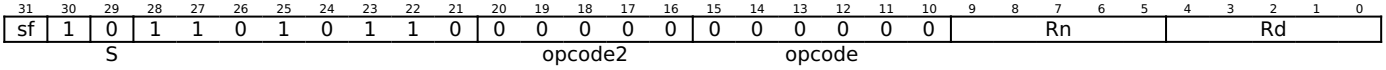
RBIT

Reverse bits

This instruction reverses the bit order in a register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
RBIT <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
RBIT <Xd>, <Xn>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand : bits(datasize) = X{datasize}(n);
var result : bits(datasize);

for i = 0 to datasize-1 do
    result[(datasize-1)-i] = operand[i];
end;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

RCWCAS, RCWCASA, RCWCASAL, RCWCASL

Read check write compare and swap doubleword in memory

This instruction reads a 64-bit doubleword from memory, and compares it against the value held in a register. If the comparison is equal, the value in a second register is conditionally written to memory. Storing back to memory is conditional on RCW Checks. If the compare fails or the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the update of memory.

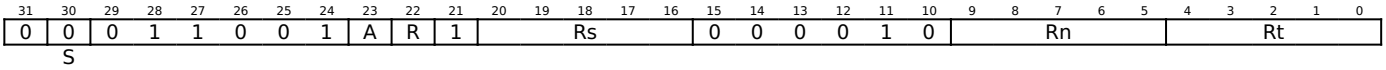
- If the destination register is not XZR, `RCWCASA` and `RCWCASAL` load from memory with acquire semantics.
- `RCWCASL` and `RCWCASAL` store to memory with release semantics.
- `RCWCAS` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

Integer

(FEAT_THE)



Encoding for the RCWCAS variant

Applies when `(A == 0 && R == 0)`

```
RCWCAS <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the RCWCASA variant

Applies when `(A == 1 && R == 0)`

```
RCWCASA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the RCWCASAL variant

Applies when `(A == 1 && R == 1)`

```
RCWCASAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the RCWCASL variant

Applies when `(A == 0 && R == 1)`

```
RCWCASL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_THE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let soft : boolean = FALSE;

let acquire : boolean = A == '1' && s != 31;
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Xs>	Is the 64-bit name of the general-purpose register to be compared and loaded, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be conditionally stored, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
if IsD128Enabled(PSTATE.EL) then Undefined(); end;
var address : bits(64);
let newdata : bits(64) = X{}(t);
let compdata : bits(64) = X{}(s);
var readdata : bits(64);
var nzcv : bits(4);

let accdesc : AccessDescriptor = CreateAccDescRCW(MemAtomicOp_CAS, soft, acquire,
                                                  release, tagchecked, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

(nzcv, readdata) = MemAtomicRCW{64}(address, compdata, newdata, accdesc);

PSTATE.[N,Z,C,V] = nzcv;
X{64}(s) = readdata;   // Return the old value when s!=31
```

RCWCASP, RCWCASPA, RCWCASPAL, RCWCASPL

Read check write compare and swap quadword in memory

This instruction reads a 128-bit quadword from memory, and compares it against the value held in a pair of registers. If the comparison is equal, the value in a second pair of registers is conditionally written to memory. Storing back to memory is conditional on RCW Checks. If the compare fails or the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the update of memory.

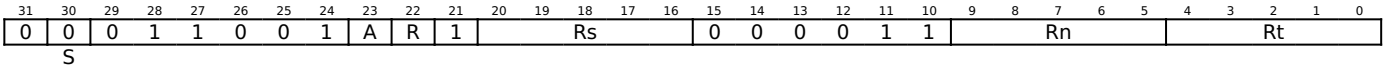
- RCWCASPA and RCWCASPAL load from memory with acquire semantics.
- RCWCASPL and RCWCASPAL store to memory with release semantics.
- RCWCASP has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

Integer

(FEAT_D128 && FEAT_THE)



Encoding for the RCWCASP variant

Applies when (A == 0 && R == 0)

```
RCWCASP <Xs>, <X(s+1)>, <Xt>, <X(t+1)>, [<Xn|SP>]
```

Encoding for the RCWCASPA variant

Applies when (A == 1 && R == 0)

```
RCWCASPA <Xs>, <X(s+1)>, <Xt>, <X(t+1)>, [<Xn|SP>]
```

Encoding for the RCWCASPAL variant

Applies when (A == 1 && R == 1)

```
RCWCASPAL <Xs>, <X(s+1)>, <Xt>, <X(t+1)>, [<Xn|SP>]
```

Encoding for the RCWCASPL variant

Applies when (A == 0 && R == 1)

```
RCWCASPL <Xs>, <X(s+1)>, <Xt>, <X(t+1)>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_D128) || !IsFeatureImplemented(FEAT_THE) then
    EndOfDecode(Decode_UNDEF);
end;
if Rs[0] == '1' then EndOfDecode(Decode_UNDEF); end;
if Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;

RCWCLR, RCWCLRA, RCWCLRAL, RCWCLRL

Read check write atomic bit clear on doubleword in memory

This instruction atomically loads a 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and conditionally stores the result back to memory. Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the destination register. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

- If the destination register is not XZR, `RCWCLRA` and `RCWCLRAL` load from memory with acquire semantics.
- `RCWCLRL` and `RCWCLRAL` store to memory with release semantics.
- `RCWCLR` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

Integer

RCWCLRP, RCWCLRPA, RCWCLRPAL, RCWCLRPL

Read check write atomic bit clear on quadword in memory

This instruction atomically loads a 128-bit quadword from memory, performs a bitwise AND with the complement of the value held in a pair of registers on it, and conditionally stores the result back to memory. Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the same pair of registers. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

- `RCWCLRPA` and `RCWCLRPAL` load from memory with acquire semantics.
- `RCWCLRPL` and `RCWCLRPAL` store to memory with release semantics.
- `RCWCLRP` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

RCWSCAS, RCWSCASA, RCWSCASAL, RCWSCASL

Read check write software compare and swap doubleword in memory

This instruction reads a 64-bit doubleword from memory, and compares it against the value held in a register. If the comparison is equal, the value in a second register is conditionally written to memory. Storing back to memory is conditional on RCW Checks and RCWS Checks. If the compare fails, the RCW Checks fail, or the RCWS Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the update of memory.

- If the destination register is not XZR, `RCWSCASA` and `RCWSCASAL` load from memory with acquire semantics.
- `RCWSCASL` and `RCWSCASAL` store to memory with release semantics.
- `RCWSCAS` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

RCWSET, RCWSETA, RCWSETAL, RCWSETL

Read check write atomic bit set on doubleword in memory

This instruction atomically loads a 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and conditionally stores the result back to memory. Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the destination register. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

- If the destination register is not XZR, `RCWSETA` and `RCWSETAL` load from memory with acquire semantics.
- `RCWSETL` and `RCWSETAL` store to memory with release semantics.
- `RCWSET` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

RCWSETP, RCWSETPA, RCWSETPAL, RCWSETPL

Read check write atomic bit set on quadword in memory

This instruction atomically loads a 128-bit quadword from memory, performs a bitwise OR with the value held in a pair of registers on it, and conditionally stores the result back to memory. Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the same pair of registers. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

- `RCWSETPA` and `RCWSETPAL` load from memory with acquire semantics.
- `RCWSETPL` and `RCWSETPAL` store to memory with release semantics.
- `RCWSETP` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

Encoding for the RCWSWPL variant

Applies when `(A == 0 && R == 1)`

```
RCWSWPL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_THE) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let soft : boolean = FALSE;

let acquire : boolean = A == '1' && t != 31;
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Xs>	Is the 64-bit name of the general-purpose register to be stored, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
if IsD128Enabled(PSTATE.EL) then Undefined(); end;
var address : bits(64);
let newdata : bits(64) = X{}(s);
var readdata : bits(64);
var nzcv : bits(4);

let accdesc : AccessDescriptor = CreateAccDescRCW(MemAtomicOp_SWP, soft, acquire,
                                                  release, tagchecked, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let compdata : bits(64) = ARBITRARY : bits(64);    // Irrelevant when not executing CAS
(nzcv, readdata) = MemAtomicRCW{64}(address, compdata, newdata, accdesc);

PSTATE.[N,Z,C,V] = nzcv;
X{64}(t) = readdata;   // Return the old value when t!=31
```

RCWSWPP, RCWSWPPA, RCWSWPPAL, RCWSWPPL

Read check write swap quadword in memory

This instruction atomically loads a 128-bit quadword from a memory location, and conditionally stores the value held in a pair of registers back to the same memory location. Storing back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the same pair of registers. If the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the RCW Checks.

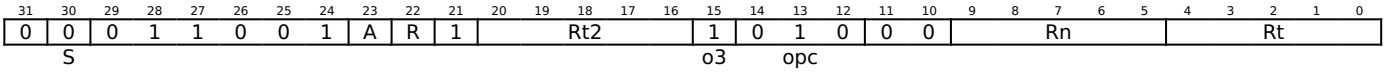
- `RCWSWPPA` and `RCWSWPPAL` load from memory with acquire semantics.
- `RCWSWPPL` and `RCWSWPPAL` store to memory with release semantics.
- `RCWSWPP` has neither acquire nor release semantics.

Note

This instruction is for performing atomic updates of translation table entries and not for general use.

Integer

(FEAT_D128 && FEAT_THE)



Encoding for the RCWSWPP variant

Applies when `(A == 0 && R == 0)`

```
RCWSWPP <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the RCWSWPPA variant

Applies when `(A == 1 && R == 0)`

```
RCWSWPPA <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the RCWSWPPAL variant

Applies when `(A == 1 && R == 1)`

```
RCWSWPPAL <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the RCWSWPPL variant

Applies when `(A == 0 && R == 1)`

```
RCWSWPPL <Xt1>, <Xt2>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_D128) || !IsFeatureImplemented(FEAT_THE) then
    EndOfDecode(Decode_UNDEF);
end;
if Rt  == '11111' then EndOfDecode(Decode_UNDEF); end;
if Rt2 == '11111' then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let soft : boolean = FALSE;

let acquire : boolean = A == '1';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;

if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LSE128OVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // result is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *128-bit Atomic Memory Operations*.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
if !IsD128Enabled(PSTATE.EL) then Undefined(); end;
var address : bits(64);
var value1 : bits(64);
var value2 : bits(64);
var newdata : bits(128);

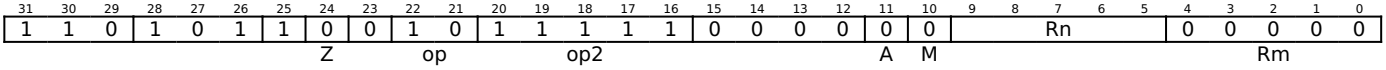
RET

Return from subroutine

This instruction branches unconditionally to an address in a register. This instruction provides a hint that this is a subroutine return.



Encoding

```
RET {<Xn>}
```

Decode for this encoding

```
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xn>	Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field. Defaults to X30 if absent.

Operation

```
var target : bits(64) = X{}(n);
if IsFeatureImplemented(FEAT_GCS) && GCSPCREnabled(PSTATE.EL) then
    target = LoadCheckGCSRecord(target, GCSInstType_PRET);
    SetCurrentGCSPointer(GetCurrentGCSPointer() + 8);
end;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';

let branch_conditional : boolean = FALSE;
BranchTo{64}(target, BranchType_RET, branch_conditional);
```

RETAA, RETAB

Return from subroutine, with pointer authentication

This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, and branches to the authenticated address.

Key A is used for `RETAA`. Key B is used for `RETAB`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

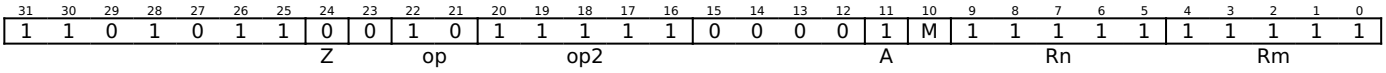
The authenticated address is not written back to LR.

This instruction provides a hint that this is a subroutine return.

If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then `RETAA` and `RETAB` include a second modifier that is in X16.

Integer

(FEAT_PAuth)



Encoding for the RETAA variant

Applies when `(M == 0)`

`RETAA`

Encoding for the RETAB variant

Applies when `(M == 1)`

`RETAB`

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let use_key_a : boolean = (M == '0');
let auth_then_branch : boolean = TRUE;
```

Operation

```
var inst_type : GCSInstruction;
var target : bits(64) = X{}(30);

let modifier : bits(64) = SP{}();
var modifier2 : bits(64);
var use_modifier2 : boolean = FALSE;
if IsFeatureImplemented(FEAT_PAuth_LR) && PSTATE.PACM == '1' then
    modifier2 = X{64}(16);
    use_modifier2 = TRUE;
end;

if use_key_a then
    if use_modifier2 && IsFeatureImplemented(FEAT_PAuth_LR) then
        target = AuthIA2(target, modifier, modifier2, auth_then_branch);
    else
        target = AuthIA(target, modifier, auth_then_branch);
    end;
else
    if use_modifier2 && IsFeatureImplemented(FEAT_PAuth_LR) then
        target = AuthIB2(target, modifier, modifier2, auth_then_branch);
    else
        target = AuthIB(target, modifier, auth_then_branch);
    end;
end;

if IsFeatureImplemented(FEAT_GCS) && GCSPCREnabled(PSTATE.EL) then
    inst_type = if use_key_a then GCSInstType_PRETAA else GCSInstType_PRETAB;
    target = LoadCheckGCSRecord(target, inst_type);
    SetCurrentGCSPointer(GetCurrentGCSPointer() + 8);
end;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';

let branch_conditional : boolean = FALSE;
BranchTo{64}(target, BranchType_RET, branch_conditional);
```

RETAASPPC, RETABSPPC

Return from subroutine, with enhanced pointer authentication using an immediate offset

This instruction authenticates the address that is held in LR, using SP as the first modifier, the specified immediate subtracted from PC as the second modifier, and the specified key, and branches to the authenticated address.

Key A is used for `RETAASPPC`. Key B is used for `RETABSPPC`.

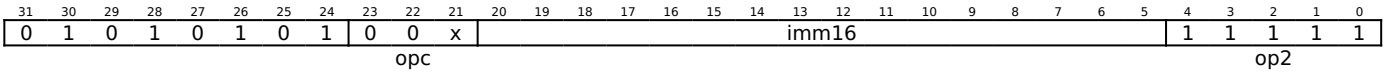
If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The authenticated address is not written back to LR.

This instruction provides a hint that this is a subroutine return.

Integer

(FEAT_PAuth_LR)



Encoding for the RETAASPPC variant

Applies when `(opc == 000)`

```
RETAASPPC <label>
```

Encoding for the RETABSPPC variant

Applies when `(opc == 001)`

```
RETABSPPC <label>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth_LR) then EndOfDecode(Decode_UNDEF); end;

let use_key_a : boolean = opc[0] == '0';
let offset : bits(64) = ZeroExtend{}(imm16::'00');
let auth_then_branch : boolean = TRUE;
```

Assembler Symbols

<label>	Is the program label whose address is to be calculated. Its negative offset from the address of this instruction, a multiple of 4 in the range -262140 to 0, is encoded as an unsigned value in the "imm16" field as <label>/4.

Operation

```
var inst_type : GCSInstruction;
var target : bits(64) = X{64}(30);

let modifier : bits(64) = SP{64}();
let modifier2 : bits(64) = PC64() - offset;

if use_key_a then
    target = AuthIA2(target, modifier, modifier2, auth_then_branch);
else
    target = AuthIB2(target, modifier, modifier2, auth_then_branch);
end;

if IsFeatureImplemented(FEAT_GCS) && GCSPCREnabled(PSTATE.EL) then
    inst_type = if use_key_a then GCSInstType_PRETAA else GCSInstType_PRETAB;
    target = LoadCheckGCSRecord(target, inst_type);
    SetCurrentGCSPointer(GetCurrentGCSPointer() + 8);
end;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';

let branch_conditional : boolean = FALSE;
BranchTo{64}(target, BranchType_RET, branch_conditional);
```

RETAASPPCR, RETABSPPCR

Return from subroutine, with enhanced pointer authentication using a register

This instruction authenticates the address that is held in LR, using SP as the first modifier, the value in the specified register as the second modifier, and the specified key, and branches to the authenticated address.

Key A is used for `RETAASPPCR`. Key B is used for `RETABSPPCR`.

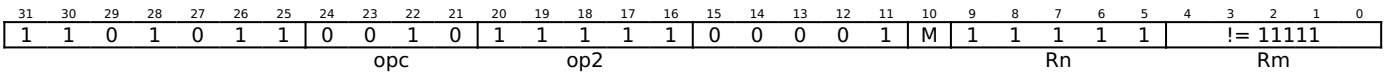
If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The authenticated address is not written back to LR.

This instruction provides a hint that this is a subroutine return.

Integer

(FEAT_PAuth_LR)



Encoding for the RETAASPPCR variant

Applies when `(M == 0)`

```
RETAASPPCR <Xm>
```

Encoding for the RETABSPPCR variant

Applies when `(M == 1)`

```
RETABSPPCR <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth_LR) then EndOfDecode(Decode_UNDEF); end;
let m : integer = UInt(Rm);
let use_key_a : boolean = M == '0';
let auth_then_branch : boolean = TRUE;
```

Assembler Symbols

<Xm>	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

```
var inst_type : GCSInstruction;
var target : bits(64) = X{64}(30);

let modifier : bits(64) = SP{64}();
let modifier2 : bits(64) = X{64}(m);

if use_key_a then
    target = AuthIA2(target, modifier, modifier2, auth_then_branch);
else
    target = AuthIB2(target, modifier, modifier2, auth_then_branch);
end;

if IsFeatureImplemented(FEAT_GCS) && GCSPCREnabled(PSTATE.EL) then
    inst_type = if use_key_a then GCSInstType_PRETAA else GCSInstType_PRETAB;
    target = LoadCheckGCSRecord(target, inst_type);
    SetCurrentGCSPointer(GetCurrentGCSPointer() + 8);
end;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';

let branch_conditional : boolean = FALSE;
BranchTo{64}(target, BranchType_RET, branch_conditional);
```

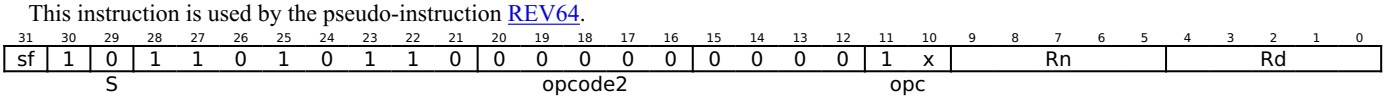
REV

Reverse bytes

This instruction reverses the byte order in a register.
This instruction is used by the pseudo-instruction REV64.



Encoding for the 32-bit variant

Applies when `(sf == 0 && opc == 10)`

```
REV <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1 && opc == 11)`

```
REV <Xd>, <Xn>
```

Decode for all variants of this encoding

```
if opc == '11' && sf == '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let container_size : integer{} = 8 << UInt(opc);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand : bits(datasize) = X{datasize}(n);
var result : bits(datasize);

let containers : integer = datasize DIV container_size;
for c = 0 to containers-1 do
    let container : bits(container_size) = operand[c*:container_size];
    result[c*:container_size] = Reverse{container_size}(container, 8);
end;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

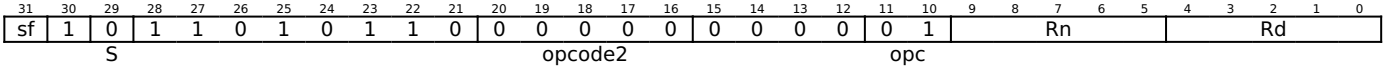
REV16

Reverse bytes in 16-bit halfwords

This instruction reverses the byte order in each 16-bit halfword of a register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
REV16 <Wd>, <Wn>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
REV16 <Xd>, <Xn>
```

Decode for all variants of this encoding

```
if opc == '11' && sf == '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let container_size : integer{} = 8 << UInt(opc);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand : bits(datasize) = X{datasize}(n);
var result : bits(datasize);

let containers : integer = datasize DIV container_size;
for c = 0 to containers-1 do
    let container : bits(container_size) = operand[c*:container_size];
    result[c*:container_size] = Reverse{container_size}(container, 8);
end;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

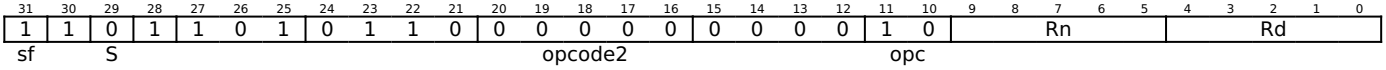
REV32

Reverse bytes in 32-bit words

This instruction reverses the byte order in each 32-bit word of a register.



Encoding

```
REV32 <Xd>, <Xn>
```

Decode for this encoding

```
if opc == '11' && sf == '0' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let container_size : integer{} = 8 << UInt(opc);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand : bits(datasize) = X{datasize}(n);
var result : bits(datasize);

let containers : integer = datasize DIV container_size;
for c = 0 to containers-1 do
    let container : bits(container_size) = operand[c*:container_size];
    result[c*:container_size] = Reverse{container_size}(container, 8);
end;

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

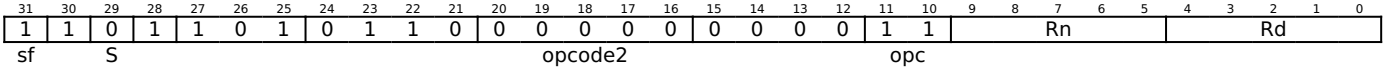
REV64

Reverse bytes

This instruction reverses the byte order in a 64-bit general-purpose register.
When assembling for Armv8.2, an assembler must support this pseudo-instruction. It is OPTIONAL whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than Armv8.2.

This is a pseudo-instruction of REV. This means:

- The encodings in this description are named to match the encodings of REV.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of REV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
REV64 <Xd>, <Xn>
```

is equivalent to

```
REV <Xd>, <Xn>
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of REV gives the operational pseudocode for this instruction.

Operational Information

The description of REV gives the operational information for this instruction.

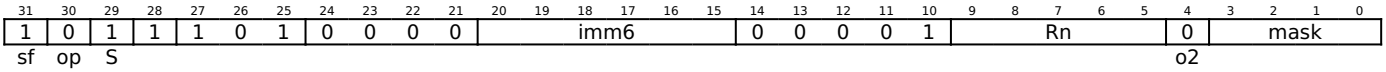
RMIF

Rotate, mask insert flags

This instruction performs a rotation right of a value held in a general-purpose register by an immediate value, and then inserts a selection of the bottom four bits of the result of the rotation into the PSTATE flags, under the control of a second immediate mask.

Integer

(FEAT_FlagM)



Encoding

```
RMIF <Xn>, #<shift>, #<mask>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_FlagM) then EndOfDecode(Decode_UNDEF); end;
let imm : integer{} = UInt(imm6);
let flagmask : bits(4) = mask;
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift>	Is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
<mask>	Is the flag bit mask, an immediate in the range 0 to 15, which selects the bits that are inserted into the NZCV condition flags, encoded in the "mask" field.

Operation

```
let reg : bits(64) = X{64}(n);
let flags : bits(4) = (reg::reg)[imm+3:imm];
if flagmask[3] == '1' then PSTATE.N = flags[3]; end;
if flagmask[2] == '1' then PSTATE.Z = flags[2]; end;
if flagmask[1] == '1' then PSTATE.C = flags[1]; end;
if flagmask[0] == '1' then PSTATE.V = flags[0]; end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

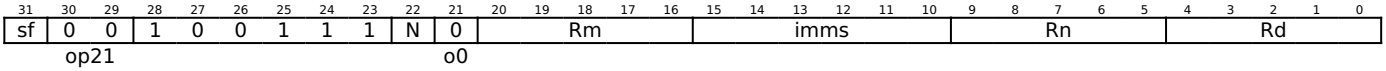
ROR (immediate)

Rotate right (immediate)

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This is an alias of EXTR. This means:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0 && imms == 0xxxxx)`

```
ROR <Wd>, <Ws>, #<shift>
```

is equivalent to

```
EXTR <Wd>, <Ws>, <Ws>, #<shift>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
ROR <Xd>, <Xs>, #<shift>
```

is equivalent to

```
EXTR <Xd>, <Xs>, <Xs>, #<shift>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Ws>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
<shift>	For the "32-bit" variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field. For the "64-bit" variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xs>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

Operation

The description of EXTR gives the operational pseudocode for this instruction.

Operational Information

The description of EXTR gives the operational information for this instruction.

2026-09_rel 2026-09-21 14:22:38

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

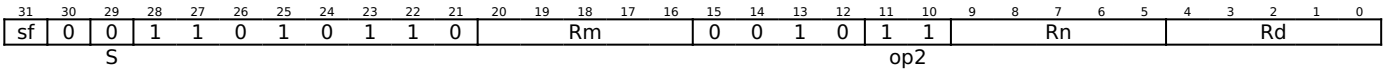
ROR (register)

Rotate right (register)

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of RORV. This means:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
ROR <Wd>, <Wn>, <Wm>
```

is equivalent to

```
RORV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
ROR <Xd>, <Xn>, <Xm>
```

is equivalent to

```
RORV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of RORV gives the operational pseudocode for this instruction.

Operational Information

The description of RORV gives the operational information for this instruction.

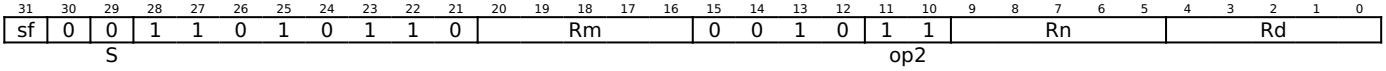
RORV

Rotate right variable

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
RORV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
RORV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(op2);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
let operand2 : bits(datasize) = X{datasize}(m);

X{datasize}(d) = ShiftReg{datasize}(n, shift_type, UInt(operand2) MOD datasize);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

RPRFM

Range prefetch memory

This instruction signals the memory system that data memory accesses from a specified range of addresses are likely to occur in the near future. The instruction may also signal the memory system about the likelihood of data reuse of the specified range of addresses. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as prefetching locations within the specified address ranges into one or more caches. The memory system may also exploit the data reuse hints to decide whether to retain the data in other caches upon eviction from the innermost caches or to discard it.

The effect of an RPRFM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory*.

An RPRFM instruction specifies the type of accesses and range of addresses using the following parameters:

- 'Access type', encoded in Rt<0>, specifies:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- 'Policy', encoded in Rt<2:1>, specifies:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once. If a streaming prefetch is specified, then the 'ReuseDistance' parameter is ignored.
- 'BaseAddress', in the 64-bit base register, holds the initial block address for the accesses.
- 'ReuseDistance', in the metadata register bits[63:60], indicates the maximum number of bytes to be accessed by this PE before executing the next RPRFM instruction that specifies the same range. This includes the total number of bytes inside and outside of the range that will be accessed by the same PE. This parameter can be used to influence cache eviction and replacement policies, in order to retain the data in the most optimal levels of the memory hierarchy after each access. If software cannot easily determine the amount of other memory that will be accessed, these bits can be set to zero to indicate that 'ReuseDistance' is not known. Otherwise, these four bits encode decreasing powers of two in the range 512MiB (0b0001) to 32KiB (0b1111).
- 'Stride', in the metadata register bits[59:38], is a signed, two's complement integer encoding of the number of bytes to advance the block address after 'Length' bytes have been accessed, in the range -2MiB to +2MiB-1B. A negative value indicates that the block address is advanced in a descending direction.
- 'Count', in the metadata register bits[37:22], is an unsigned integer encoding of the number of blocks of data to be accessed minus 1, representing the range 1 to 65536 blocks. If 'Count' is 0, then the 'Stride' parameter is ignored and only a single block of contiguous bytes from 'BaseAddress' to ('BaseAddress' + 'Length' - 1) is described.
- 'Length', in the metadata register bits[21:0], is a signed, two's complement integer encoding of the number of contiguous bytes to be accessed starting from the current block address, without changing the block address, in the range -2MiB to +2MiB-1B. A negative value indicates that the bytes are accessed in a descending direction.

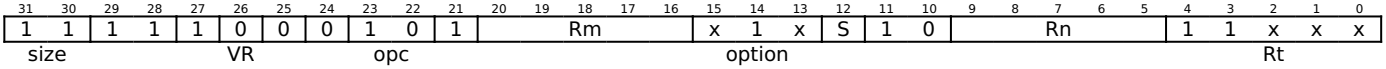
Note

Software is expected to honor the parameters it provides to the RPRFM instruction, and the same PE should access all locations in the range, in the direction specified by the sign of the 'Length' and 'Stride' parameters. A range prefetch is considered active on a PE until all locations in the range have been accessed by the PE. A range prefetch might also be inactivated by the PE prior to completion, for example due to a software context switch or lack of hardware resources.

Software should not specify overlapping addresses in multiple active ranges. If a range is expected to be accessed by both load and store instructions (read-modify-write), then a single range with an 'Access type' parameter of PST (prefetch for store) should be specified.

Integer

(FEAT_RPRFM)



Encoding

```
RPRFM  (<rprfop>|#<imm6>), <Xm>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_RPRFM) then EndOfDecode(Decode_NOP); end;
let operation : bits(6) = option[2]::option[0]::S::Rt[2:0];
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
```

Assembler Symbols

<rprfop> Is the range prefetch operation, encoded in “(option :: S :: Rt)”:

option	S	Rt	<rprfop>
010	0	11000	PLDKEEP
010	0	11001	PSTKEEP
010	0	11100	PLDSTRM
010	0	11101	PSTSTRM

For other encodings, use <imm6>.

<imm6> Is the range prefetch operation encoding as an immediate, in the range 0 to 63, encoded in "option<2>:option<0>:S:Rt<2:0>". This syntax is only for encodings that are not representable using <rprfop>.

<Xm> Is the 64-bit name of the general-purpose register that holds an encoding of the metadata, encoded in the "Rm" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
let address : bits(64)  = if n == 31 then SP{64}() else X{64}(n);
let metadata : bits(64) = X{}(m);
let stride : integer = SInt(metadata[59:38]);
let count : integer  = UInt(metadata[37:22]) + 1;
let length : integer = SInt(metadata[21:0]);
var reuse : integer;

if metadata[63:60] == '0000' then
    reuse = -1; // Not known
else
    reuse = 32768 << (15 - UInt(metadata[63:60]));
end;

Hint_RangePrefetch(address, length, stride, count, reuse, operation);
```

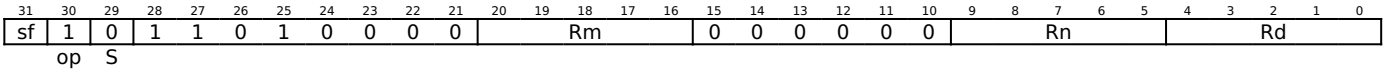
SBC

Subtract with carry

This instruction subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. This instruction is used by the alias NGC.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SBC <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SBC <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
NGC	`Rn == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = NOT X{datasize}(m);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, PSTATE.C);

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

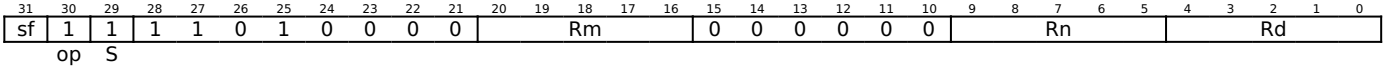
SBCS

Subtract with carry, setting flags

This instruction subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias NGCS.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SBCS <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SBCS <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
NGCS	`Rn == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = NOT X{datasize}(m);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, PSTATE.C);

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

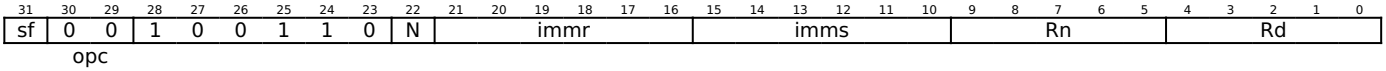
SBFIZ

Signed bitfield insert in zeros

This instruction copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits below the bitfield to zero, and the bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

SBFM

Signed bitfield move

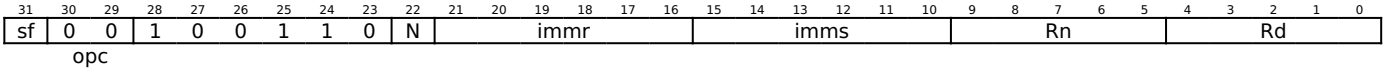
This instruction is usually accessed using one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SBFM <Wd>, <Wn>, #<immr>, #<imms>
```

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SBFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
if sf == '1' && N != '1' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && (N != '0' || immr[5] != '0' || imms[5] != '0') then
    EndOfDecode(Decode_UNDEF);
end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let s : integer = UInt(imms);
let r : integer = UInt(immr);

var wmask : bits(datasize);
var tmask : bits(datasize);
(wmask, tmask) = DecodeBitMasks{datasize}(N, imms, immr, FALSE);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<immr>	For the "32-bit" variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the "64-bit" variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
<imms>	For the "32-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the "64-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Of variant	Is preferred when
ASR (immediate)	32-bit	`imms == '011111'`
ASR (immediate)	64-bit	`imms == '111111'`
SBFIZ		`UInt(imms) < UInt(immr)`
SBFX		`BFXPreferred(sf, opc[1], imms, immr)`
SXTB		`immr == '000000' && imms == '000111'`
SXTH		`immr == '000000' && imms == '001111'`
SXTW		`immr == '000000' && imms == '011111'`

Operation

```
let src : bits(datasize) = X{}(n);

// Perform bitfield move on low bits
let bot : bits(datasize) = ROR(src, r) AND wmask;
let top : bits(datasize) = Replicate{}(src[s]);

// Combine extension bits and result bits
X{datasize}(d) = (top AND NOT tmask) OR (bot AND tmask);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

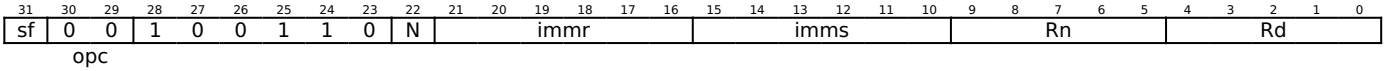
SBFX

Signed bitfield extract

This instruction copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SBFX <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc[1], imms, immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SBFX <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc[1], imms, immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

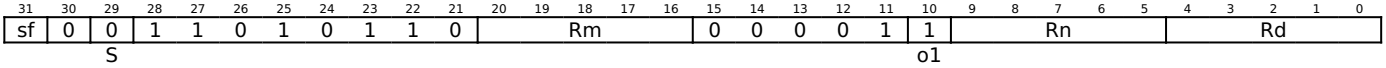
SDIV (quotient)

Signed divide

This instruction divides the first signed source register value by the second signed source register value, and writes the result to the destination register. Dividing by zero writes the value zero to the destination register. The condition flags are not affected.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SDIV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SDIV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let dividend : integer = SInt(operand1);
let divisor : integer = SInt(operand2);

var result : integer;
if divisor == 0 then
    result = 0;
elsif dividend < 0 == divisor < 0 then
    result = Abs(dividend) DIVRM Abs(divisor);    // same signs - positive result
else
    result = -(Abs(dividend) DIVRM Abs(divisor)); // different signs - negative result
end;

X{datasize}(d) = result[datasize-1:0];
```

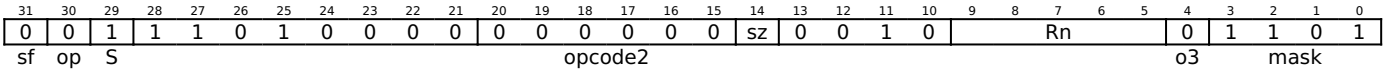
SETF8, SETF16

Evaluation of 8-bit or 16-bit flag values

This instruction sets the PSTATE.NZV flags based on the value in the specified general-purpose register. `SETF8` treats the value as an 8-bit value. `SETF16` treats the value as a 16-bit value.
The PSTATE.C flag is not affected by these instructions.

Integer

(FEAT_FlagM)



Encoding for the SETF8 variant

Applies when `(sz == 0)`

```
SETF8 <Wn>
```

Encoding for the SETF16 variant

Applies when `(sz == 1)`

```
SETF16 <Wn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FlagM) then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = 8 << UInt(sz);
let n : integer = UInt(Rn);
```

Assembler Symbols

<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let reg : bits(32) = X{32}(n);
PSTATE.N = reg[size-1];
PSTATE.Z = if reg[size-1:0] == Zeros{size} then '1' else '0';
PSTATE.V = reg[size] XOR reg[size-1];
//PSTATE.C unchanged;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

SETGP, SETGM, SETGE

Memory set with tag setting

These instructions set a requested number of bytes in memory to the value in the least significant byte of the source data register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register that holds the first address to be set. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGP, then SETGM, and then SETGE.

SETGP performs some preconditioning of the arguments suitable for using the SETGM instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETGM sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETGE sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see *Memory Copy and Memory Set exceptions*.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETGP:

- If Xn[63] == '1', the set size is saturated to 0x7FFFFFFFFFFFFF0.

On completion of SETGP, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETGP, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETGM, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETGM, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETGE, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETGE, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

SETGPN, SETGMN, SETGEN

Memory set with tag setting, non-temporal

These instructions set a requested number of bytes in memory to the value in the least significant byte of the source data register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register that holds the first address to be set. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPN, then SETGMN, and then SETGEN.

SETGPN performs some preconditioning of the arguments suitable for using the SETGMN instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETGMN sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETGEN sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see *Memory Copy and Memory Set exceptions*.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETGPN:

- If Xn[63] == '1', the set size is saturated to 0x7FFFFFFFFFFFFF0.

On completion of SETGPN, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETGPN, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETGMN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETGMN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETGEN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETGEN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

SETGPT, SETGMT, SETGET

Memory set with tag setting, unprivileged

These instructions set a requested number of bytes in memory to the value in the least significant byte of the source data register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register that holds the first address to be set. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPT, then SETGMT, and then SETGET.

SETGPT performs some preconditioning of the arguments suitable for using the SETGMT instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETGMT sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETGET sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see *Memory Copy and Memory Set exceptions*.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETGPT:

- If Xn[63] == '1', the set size is saturated to 0x7FFFFFFFFFFFFF0.

On completion of SETGPT, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETGPT, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETGMT, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETGMT, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETGET, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETGET, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.

- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

SETGPTN, SETGMTN, SETGETN

Memory set with tag setting, unprivileged and non-temporal

These instructions set a requested number of bytes in memory to the value in the least significant byte of the source data register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register that holds the first address to be set. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPTN, then SETGMTN, and then SETGETN.

SETGPTN performs some preconditioning of the arguments suitable for using the SETGMTN instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETGMTN sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETGETN sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see *Memory Copy and Memory Set exceptions*.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETGPTN:

- If Xn[63] == '1', the set size is saturated to 0x7FFFFFFFFFFFFF0.

On completion of SETGPTN, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETGPTN, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETGMTN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETGMTN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETGETN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETGETN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.

- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

SETP, SETM, SETE

Memory set

These instructions set a required number of bytes in memory to the value in the least significant byte of the source data register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETP, then SETM, and then SETE.

SETP performs some preconditioning of the arguments suitable for using the SETM instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETM sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETE sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see *Memory Copy and Memory Set exceptions*.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETP:

- If Xn[63] == '1', the set size is saturated to 0x7FFFFFFFFFFFFFFF.

On completion of SETP, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETP, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETM, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETM, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETE, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETE, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

SETPN, SETMN, SETEN

Memory set, non-temporal

These instructions set a required number of bytes in memory to the value in the least significant byte of the source data register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPN, then SETMN, and then SETEN.
SETPN performs some preconditioning of the arguments suitable for using the SETMN instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETMN sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETEN sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETPN:

- If Xn[63] == '1', the set size is saturated to 0x7FFFFFFFFFFFFFFF.

On completion of SETPN, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETPN, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETMN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETMN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETEN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETEN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

SETPT, SETMT, SETET

Memory set, unprivileged

These instructions set a required number of bytes in memory to the value in the least significant byte of the source data register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPT, then SETMT, and then SETET.
SETPT performs some preconditioning of the arguments suitable for using the SETMT instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETMT sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETET sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETPT:

- If Xn[63] == '1', the set size is saturated to 0x7FFFFFFFFFFFFFFF.

On completion of SETPT, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETPT, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETMT, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETMT, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETET, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETET, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

SETPTN, SETMTN, SETETN

Memory set, unprivileged and non-temporal

These instructions set a required number of bytes in memory to the value in the least significant byte of the source data register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPTN, then SETMTN, and then SETETN.
SETPTN performs some preconditioning of the arguments suitable for using the SETMTN instruction, and sets an IMPLEMENTATION DEFINED portion of the requested number of bytes. SETMTN sets a further IMPLEMENTATION DEFINED portion of the remaining bytes. SETETN sets any final remaining bytes.

Note

The ability to set an IMPLEMENTATION DEFINED number of bytes allows an implementation to optimize how the bytes being set are divided between the different instructions.

For more information on exceptions specific to memory set instructions, see *Memory Copy and Memory Set exceptions*.
The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

For SETPTN:

- If Xn[63] == '1', the set size is saturated to 0x7FFFFFFFFFFFFFFF.

On completion of SETPTN, option A:

- Xn holds -1 times the number of bytes in the saturated set size remaining to be set.
- Xd holds the original Xd + saturated set size.
- PSTATE.{N,Z,C,V} are set to {0,0,0,0}.

On completion of SETPTN, option B:

- Xn holds the number of bytes in the saturated set size remaining to be set.
- Xd holds the lowest address that has not been set.
- PSTATE.{N,Z,C,V} are set to {0,0,1,0}.

For SETMTN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds -1 times the number of bytes remaining to be set.

For SETMTN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds the number of bytes remaining to be set.
  - Xd holds the lowest address that has not been set.

For SETETN, option A, when PSTATE.C = '0':

- Xn holds a signed 64-bit integer.
- Xn holds -1 times the number of bytes remaining to be set.
- Xd holds the lowest address to be set - Xn.
- On completion of the instruction, Xn holds 0.

For SETETN, option B, when PSTATE.C = '1':

- Xn holds the number of bytes remaining to be set.
- Xd holds the lowest address to be set.
- On completion of the instruction:
  - Xn holds 0.
  - Xd holds the lowest address that has not been set.

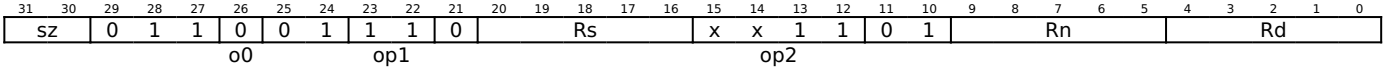
Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_MOPS)



Encoding for the Prologue variant

Applies when `(op2 == 0011)`

```
SETPTN [<Xd>]!, <Xn>!, <Xs>
```

Encoding for the Main variant

Applies when `(op2 == 0111)`

```
SETMTN [<Xd>]!, <Xn>!, <Xs>
```

Encoding for the Epilogue variant

Applies when `(op2 == 1011)`

```
SETETN [<Xd>]!, <Xn>!, <Xs>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_MOPS) || sz != '00' then EndOfDecode(Decode_UNDEF); end;

var memset : SETParams;
memset.d = UInt(Rd);
memset.s = UInt(Rs);
memset.n = UInt(Rn);
let options : bits(2) = op2[1:0];
let nontemporal : boolean = options[1] == '1';

case op2[3:2] of
    when '00' => memset.stage = MOPSStage_Prologue;
    when '01' => memset.stage = MOPSStage_Main;
    when '10' => memset.stage = MOPSStage_Epilogue;
    otherwise => EndOfDecode(Decode_UNDEF);
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *Memory Copy and Memory Set SET** and *Crossing a page boundary with different memory types or Shareability attributes*.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address and for option B is updated by the instruction, encoded in the "Rd" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be set and is updated by the instruction, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be set and is updated by the instruction, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be set and is set to zero on completion of the instruction, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register that holds the source data, encoded in the "Rs" field.

Operation

```
CheckMOPSEnabled();

CheckSETConstrainedUnpredictable(memset);

let data : bits(8) = X{}(memset.s);

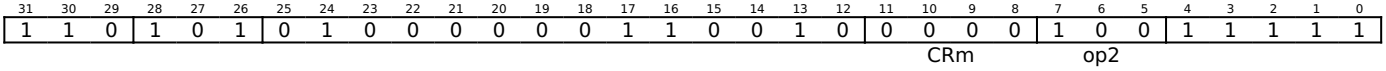
SEV

Send event

This instruction is a hint instruction that causes an event to be signaled to all PEs in the multiprocessor system. For more information, see *Wait for Event mechanism and Send event*.



Encoding

SEV

Decode for this encoding

```
// Empty.
```

Operation

```
SendEvent();
```

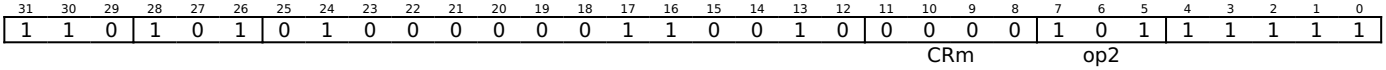
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

SEVL

Send event local

This instruction is a hint instruction that causes an event to be signaled locally without requiring the event to be signaled to other PEs in the multiprocessor system. It can prime a wait-loop that starts with a `WFE` instruction.



Encoding

```
SEVL
```

Decode for this encoding

```
// Empty.
```

Operation

```
SendEventLocal();
```

SHUH

Shared update hint

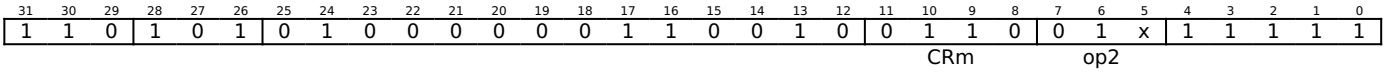
This instruction signals to the memory system that if the next instruction in program order generates an Explicit Memory Effect, then it is to a location that one or more other threads of execution are likely to subsequently update, and there is a performance benefit to ensuring subsequent updates by other threads of execution complete with minimal latency.

Note

This instruction might increase the latency of subsequent accesses to the location by the executing PE.

System

(FEAT_CMH)



Encoding

```
SHUH {PH}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CMH) then EndOfDecode(Decode_NOP); end;
let priority : boolean = op2[0] == '1';
```

Assembler Symbols

PH — Is a priority hint. If present, it additionally provides the same hint as the STCPH instruction, and is encoded in "op2[0]":

op2[0]	PH
0	[absent]
1	[present]

Operation

```
Hint_SharedUpdate(priority);
```

SLBND

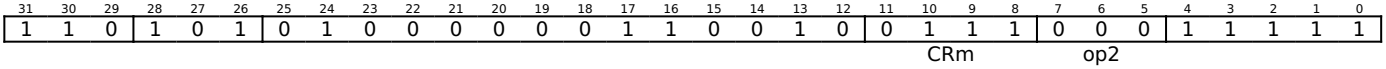
Scoped release boundary

This instruction signals to the memory system that a corresponding instruction with Release semantics or DMB instruction will subsequently occur in program order, and if that corresponding instruction defines a Barrier scope with the SLBND instruction, then these instructions do not create a Barrier-ordered-before relationship between any Effect in program order before the SLBND instruction and any of the following:

- The Effect with Release semantics.
- Any Effect in program order after the DMB Effect.

System

(FEAT_RLCS)



Encoding

SLBND

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_RLCS) then EndOfDecode(Decode_NOP); end;
```

Operation

```
Hint_ScopedReleaseBoundary();
```

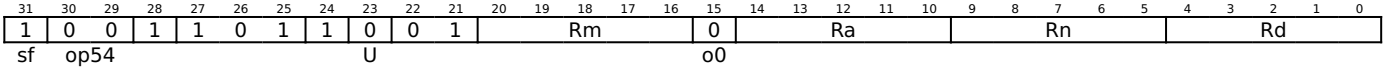
SMADDL

Signed multiply-add long

This instruction multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.
This instruction is used by the alias SMULL (32-bit).



Encoding

```
SMADDL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
SMULL (32-bit)	`Ra == '11111'`

Operation

```
let operand1 : bits(32) = X{32}(n);
let operand2 : bits(32) = X{32}(m);
let operand3 : bits(64) = X{64}(a);

let result : integer = SInt(operand3) + SInt(operand1) * SInt(operand2);

X{64}(d) = result[63:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

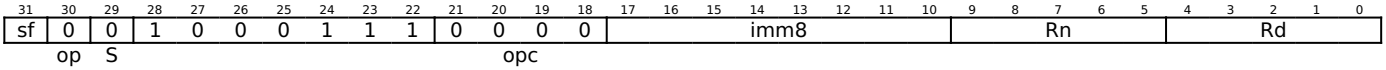
SMAX (immediate)

Signed maximum (immediate)

This instruction determines the signed maximum of the source register value and immediate, and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SMAX <Wd>, <Wn>, #<simm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SMAX <Xd>, <Xn>, #<simm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let imm : integer = SInt(imm8);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<simm>	Is a signed immediate, in the range -128 to 127, encoded in the "imm8" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = Max(SInt(operand1), imm);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

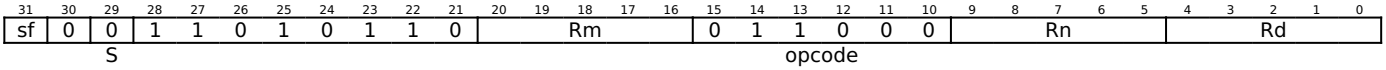
SMAX (register)

Signed maximum (register)

This instruction determines the signed maximum of the two source register values and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SMAX <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SMAX <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let result : integer = Max(SInt(operand1), SInt(operand2));

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

SMC

Secure monitor call

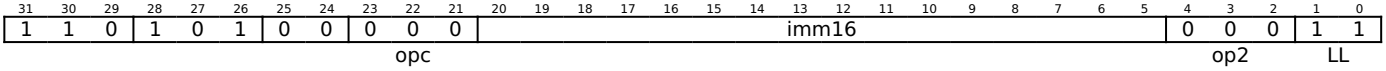
This instruction causes an exception to EL3.

SMC is available only for software executing at EL1 or higher. It is UNDEFINED at EL0.

If the values of *HCR_EL2*.TSC and SCR_EL3.SMD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in *ESR_ELx*, using the EC syndrome value 0x17, that is taken to EL3.

If the value of *HCR_EL2*.TSC is 1 and EL2 is enabled in the current Security state, execution of an SMC instruction at EL1 generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD.

If the value of *HCR_EL2*.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is UNDEFINED.



Encoding

```
SMC #<imm>
```

Decode for this encoding

```
let imm : bits(16) = imm16;
```

Assembler Symbols

<imm>	Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
if PSTATE.EL == EL0 then Undefined(); end;
AArch64_CheckForSMCUndefOrTrap(imm);
AArch64_CallSecureMonitor(imm);
```

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

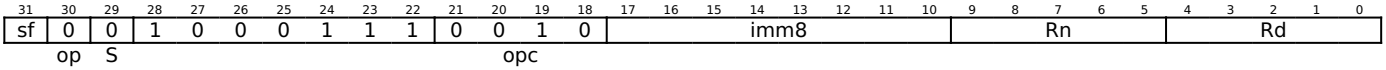
SMIN (immediate)

Signed minimum (immediate)

This instruction determines the signed minimum of the source register value and immediate, and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SMIN <Wd>, <Wn>, #<simm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SMIN <Xd>, <Xn>, #<simm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let imm : integer = SInt(imm8);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<simm>	Is a signed immediate, in the range -128 to 127, encoded in the "imm8" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = Min(SInt(operand1), imm);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

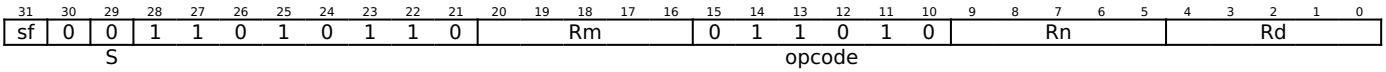
SMIN (register)

Signed minimum (register)

This instruction determines the signed minimum of the two source register values and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SMIN <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SMIN <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let result : integer = Min(SInt(operand1), SInt(operand2));

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

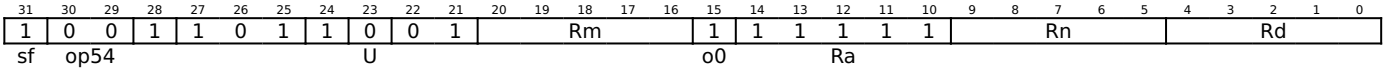
SMNEGL

Signed multiply-negate long

This instruction multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This is an alias of SMSUBL. This means:

- The encodings in this description are named to match the encodings of SMSUBL.
- The description of SMSUBL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
SMNEGL <Xd>, <Wn>, <Wm>
```

is equivalent to

```
SMSUBL <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMSUBL gives the operational pseudocode for this instruction.

Operational Information

The description of SMSUBL gives the operational information for this instruction.

SMSTART

Enable access to Streaming SVE mode and SME architectural state

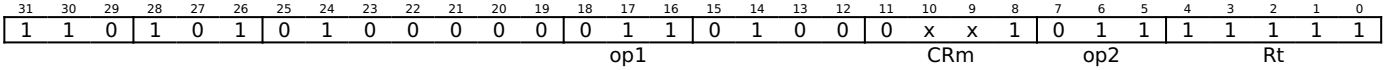
This instruction enables access to Streaming SVE mode and SME architectural state.
SMSTART enters Streaming SVE mode, and enables the SME ZA storage.
SMSTART SM enters Streaming SVE mode, but does not enable the SME ZA storage.
SMSTART ZA enables the SME ZA storage, but does not cause an entry to Streaming SVE mode.

This is an alias of MSR (immediate). This means:

- The encodings in this description are named to match the encodings of MSR (immediate).
- The description of MSR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SME)



Encoding

```
SMSTART {<option>}
```

is equivalent to

```
MSR <pstatefield>, #1
```

and is always the preferred disassembly.

SMSTOP

Disable access to Streaming SVE mode and SME architectural state

This instruction disables access to Streaming SVE mode and SME architectural state.
SMSTOP exits Streaming SVE mode, and disables the SME ZA storage.
SMSTOP SM exits Streaming SVE mode, but does not disable the SME ZA storage.
SMSTOP ZA disables the SME ZA storage, but does not cause an exit from Streaming SVE mode.

This is an alias of MSR (immediate). This means:

- The encodings in this description are named to match the encodings of MSR (immediate).
- The description of MSR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

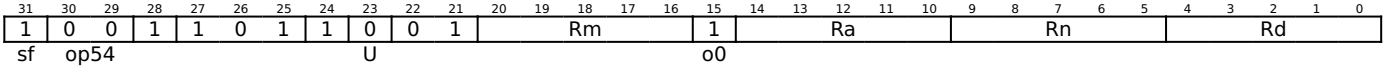
SMSUBL

Signed multiply-subtract long

This instruction multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL.



Encoding

```
SMSUBL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
SMNEGL	`Ra == '11111'`

Operation

```
let operand1 : bits(32) = X{32}(n);
let operand2 : bits(32) = X{32}(m);
let operand3 : bits(64) = X{64}(a);

let result : integer = SInt(operand3) - SInt(operand1) * SInt(operand2);

X{64}(d) = result[63:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

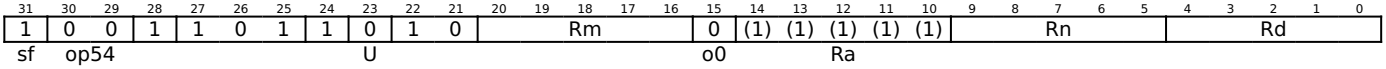
SMULH

Signed multiply high

This instruction multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.



Encoding

```
SMULH <Xd>, <Xn>, <Xm>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
let operand1 : bits(64) = X{64}(n);
let operand2 : bits(64) = X{64}(m);

let result : integer = SInt(operand1) * SInt(operand2);

X{64}(d) = result[127:64];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

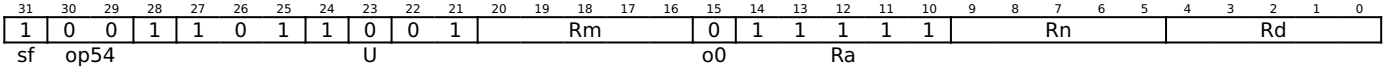
SMULL (32-bit)

Signed multiply long

This instruction multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This is an alias of SMADDL. This means:

- The encodings in this description are named to match the encodings of SMADDL.
- The description of SMADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

`SMULL <Xd>, <Wn>, <Wm>`

is equivalent to

`SMADDL <Xd>, <Wn>, <Wm>, XZR`

and is always the preferred disassembly.

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMADDL gives the operational pseudocode for this instruction.

Operational Information

The description of SMADDL gives the operational information for this instruction.

SRLS

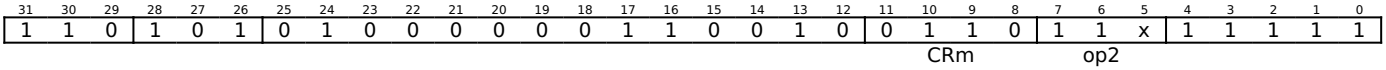
Scope release

This instruction signals to the memory system that if the next instruction in program order has Release semantics or is a DMB instruction that defines a Barrier scope with a preceding SLBND instruction, then these instructions do not create a Barrier-ordered-before relationship between any Effect in program order before the SLBND instruction and any of the following:

- The Effect with Release semantics.
- Any Effect in program order after the DMB Effect.

System

(FEAT_RLCS)



Encoding

```
SRLS {STSHSTRM}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_RLCS) then EndOfDecode(Decode_NOP); end;
let stshstrm : boolean = op2[0] == '1';
```

Assembler Symbols

STSHSTRM — Is a store shared stream hint, and is encoded in "op2[0]". If present, it additionally provides the same hint as the STSHH STRM instruction.

Note

If FEAT_PCDPHINT is not implemented, the optional STSHSTRM hint may not have the performance benefits that are associated with the hint generated by the STSHH STRM instruction.

op2[0]	STSHSTRM
0	[absent]
1	[present]

Operation

```
Hint_ScopeRelease(stshstrm);
```

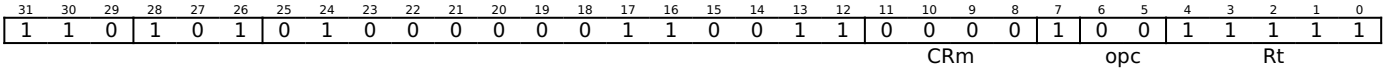
SSBB

Speculative store bypass barrier

This instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions. For more information and details of the semantics, see *Speculative Store Bypass Barrier (SSBB)*.

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

SSBB

is equivalent to

DSB #0

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.

ST2G

Store Allocation Tags

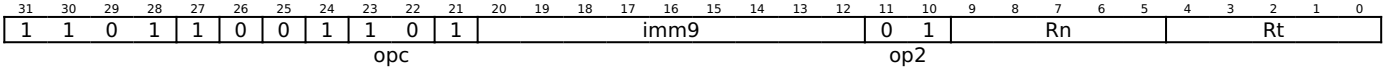
This instruction stores an Allocation Tag to two Tag Granules of memory. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag Granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index

(FEAT_MTE)



Encoding

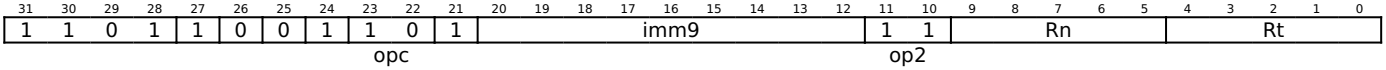
```
ST2G <Xt|SP>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = TRUE;
let postindex : boolean = TRUE;
```

Pre-index

(FEAT_MTE)



Encoding

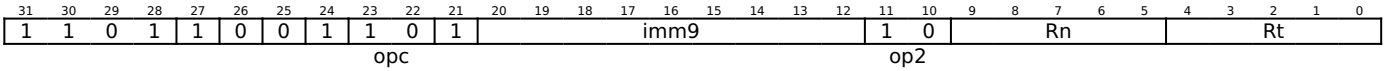
```
ST2G <Xt|SP>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = TRUE;
let postindex : boolean = FALSE;
```

Signed offset

(FEAT_MTE)



Encoding

```
ST2G <Xt|SP>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = FALSE;
let postindex : boolean = FALSE;
```

Assembler Symbols

<Xt|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate offset, a multiple of 16 in the range -4096 to 4080, defaulting to 0 and encoded in the "imm9" field.

Operation

```
var address : bits(64);
var address2 : bits(64);
let data : bits(64) = if t == 31 then SP{64}() else X{64}(t);
let tag : bits(4) = AArch64_AllocationTagFromAddress(data);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let stzgm : boolean = FALSE;
let accdesc : AccessDescriptor = CreateAccDescLDGSTG(MemOp_STORE, stzgm, t);

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

address2 = AddressIncrement(address, TAG_GRANULE, accdesc);

AArch64_MemTag(address, accdesc) = tag;
AArch64_MemTag(address2, accdesc) = tag;

if writeback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    end;

    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

ST64B

Single-copy atomic 64-byte store without status result

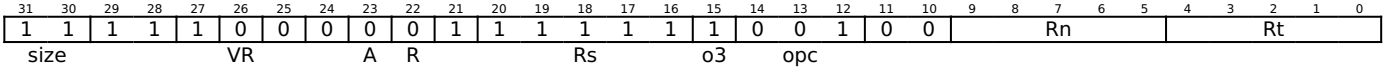
This instruction stores eight 64-bit doublewords from consecutive registers to a memory location. The store starts at register Xt, with the data being formed as Data[511:0] = X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt. The data is stored atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `ST64B` also supports `LD64B`, `LDA64B`, and `STL64B`.

For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

Integer

(FEAT_LS64)



Encoding

```
ST64B <Xt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LS64) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = FALSE;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *ST64B*.

Assembler Symbols

<Xt>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
CheckLDST64BEnabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_STORE, withstatus, acqrel, tagchecked);

for i = 0 to 7 do
    value = X{64}(t+i);
    if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;
    data[63+64*i : 64*i] = value;
end;

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

MemStore64B(address, data, accdesc);
```

ST64BV

Single-copy atomic 64-byte store with status result

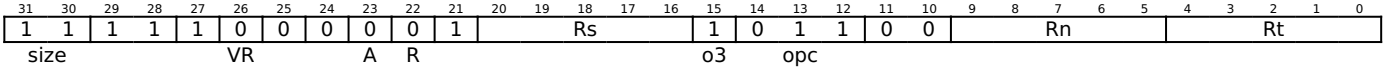
This instruction stores eight 64-bit doublewords from consecutive registers to a memory location, and writes the status result of the store to a register. The store starts at register Xt, with the data being formed as Data[511:0] = X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt. The data is stored atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports ST64BV also supports ST64BV0, STL64BV, and STL64BV0.

For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

Integer

(FEAT_LS64_V)



Encoding

```
ST64BV <Xs>, <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LS64_V) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = TRUE;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = FALSE;
```

Assembler Symbols

<Xs> Is the 64-bit name of the general-purpose register into which the status result of this instruction is written, encoded in the "Rs" field. The value returned is:

0xFFFFFFFFFFFFFFFF
: If the memory location accessed does not support this instruction. In this case, the value at the memory location is UNKNOWN.

!= 0xFFFFFFFFFFFFFFFF
: If the memory location accessed does support this instruction. In this case, the peripheral that provides the response defines the returned value and provides information on the state of the memory update at the memory location.

If XZR is used, then the return value is ignored.

<Xt> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
CheckST64BVEnabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_STORE, withstatus, acqrel, tagchecked);

for i = 0 to 7 do
    value = X{64}(t+i);
    if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;
    data[63+64*i : 64*i] = value;
end;

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let status : bits(64) = MemStore64BWithRet(address, data, accdesc);

if s != 31 then X{64}(s) = status; end;
```

ST64BV0

Single-copy atomic 64-byte EL0 store with status result

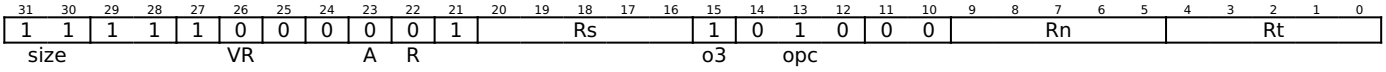
This instruction stores eight 64-bit doublewords from consecutive registers to a memory location, with the bottom 32 bits taken from ACCDATA_EL1, and writes the status result of the store to a register. The store starts at register Xt, with the data being formed as Data[511:0] = X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt[63:32]::ACCDATA_EL1()[31:0]. The data is stored atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `ST64BV0` also supports `ST64BV`, `STL64BV`, and `STL64BV0`.

For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

Integer

(FEAT_LS64_ACCDATA)



Encoding

```
ST64BV0 <Xs>, <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LS64_ACCDATA) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = TRUE;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = FALSE;
```

Assembler Symbols

<Xs> Is the 64-bit name of the general-purpose register into which the status result of this instruction is written, encoded in the "Rs" field. The value returned is:

0xFFFFFFFFFFFFFFFF
: If the memory location accessed does not support this instruction. In this case, the value at the memory location is UNKNOWN.

!= 0xFFFFFFFFFFFFFFFF
: If the memory location accessed does support this instruction. In this case, the peripheral that provides the response defines the returned value and provides information on the state of the memory update at the memory location.

If XZR is used, then the return value is ignored.

<Xt> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
CheckST64BV0Enabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_STORE, withstatus, acqrel, tagchecked);

let Xt : bits(64) = X{}(t);
value[31:0] = ACCDATA_EL1()[31:0];
value[63:32] = Xt[63:32];
if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;
data[63:0] = value;

for i = 1 to 7 do
    value = X{64}(t+i);
    if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;

STADD, STADDL

Atomic add on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory.

- `STADD` does not have release semantics.
- `STADDL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

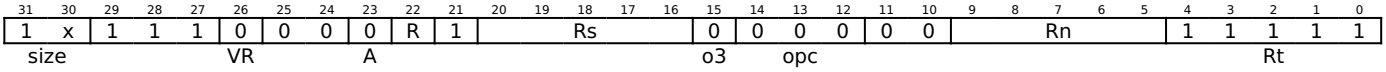
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDADD, LDADDA, LDADDAL, LDADDL. This means:

- The encodings in this description are named to match the encodings of LDADD, LDADDA, LDADDAL, LDADDL.
- The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && R == 0)`

```
STADD <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADD <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant

Applies when `(size == 10 && R == 1)`

```
STADDL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && R == 0)`

```
STADD <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDADD <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant

Applies when `(size == 11 && R == 1)`

```
STADDL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDADDL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

Operation

The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

Operational Information

The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational information for this instruction.

STCLR, STCLRL

Atomic bit clear on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

- `STCLR` does not have release semantics.
- `STCLRL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

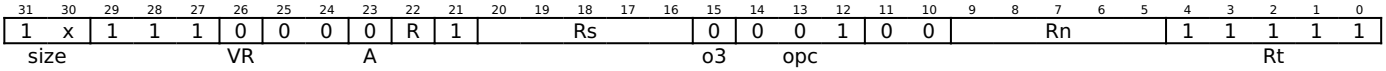
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL. This means:

- The encodings in this description are named to match the encodings of LDCLR, LDCLRA, LDCLRAL, LDCLRL.
- The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && R == 0)`

```
STCLR <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLR <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant

Applies when `(size == 10 && R == 1)`

```
STCLRL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLRL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && R == 0)`

```
STCLR <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDCLR <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant

Applies when `(size == 11 && R == 1)`

```
STCLRL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDCLRL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

Operation

The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode for this instruction.

Operational Information

The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational information for this instruction.

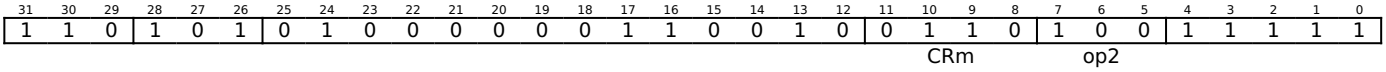
STCPH

Store concurrent priority hint

This instruction signals to the memory system that if the next instruction in program order generates an Explicit Memory Write Effect, then there is a performance benefit if that Explicit Memory Write Effect is sequenced before Memory Effects from other threads of execution in the coherence order to the same location. For atomic instructions, there is a performance benefit if the corresponding Explicit Memory Read Effect is sequenced before Memory Effects from other threads of execution in the coherence order to the same location. This includes cases in which any instruction that conditionally performs a write generates an Explicit Memory Read Effect before it is known whether the write is performed.

System

(FEAT_CMH)



Encoding

STCPH

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CMH) then EndOfDecode(Decode_NOP); end;
```

Operation

```
Hint_StoreConcurrentPriority();
```

STG

Store Allocation Tag

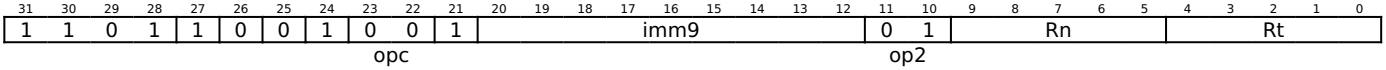
This instruction stores an Allocation Tag to memory. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag Granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index

(FEAT_MTE)



Encoding

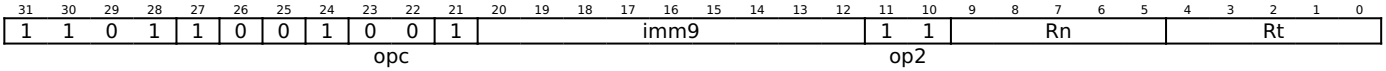
```
STG <Xt|SP>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = TRUE;
let postindex : boolean = TRUE;
```

Pre-index

(FEAT_MTE)



Encoding

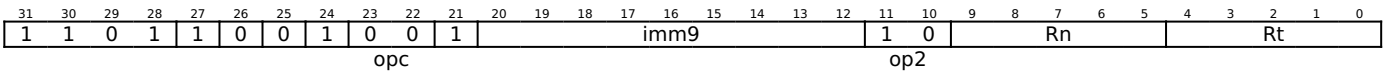
```
STG <Xt|SP>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = TRUE;
let postindex : boolean = FALSE;
```

Signed offset

(FEAT_MTE)



Encoding

```
STG <Xt|SP>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = FALSE;
let postindex : boolean = FALSE;
```

Assembler Symbols

<Xt|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate offset, a multiple of 16 in the range -4096 to 4080, defaulting to 0 and encoded in the "imm9" field.

Operation

```
var address : bits(64);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let stzgm : boolean = FALSE;
let accdesc : AccessDescriptor = CreateAccDescLDGSTG(MemOp_STORE, stzgm, t);

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

let data : bits(64) = if t == 31 then SP{64}() else X{64}(t);
let tag : bits(4) = AArch64_AllocationTagFromAddress(data);
AArch64_MemTag(address, accdesc) = tag;

STGM

Store Allocation Tag multiple

This instruction writes a naturally aligned block of N Allocation Tags, where the size of N is identified in GMID_EL1.BS, and the Allocation Tag written to address A is taken from the source register at 4*A<7:4>+3:4*A<7:4>.

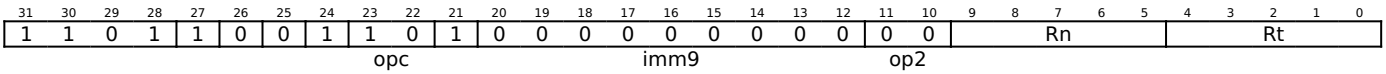
If the value of HCR_EL2.TGE is 0 and the Effective value of SCTLR2_EL1.GM0 is 0, this instruction is UNDEFINED at EL0.

If the value of HCR_EL2.TGE is 1 and the Effective value of SCTLR2_EL2.GM0 is 0, this instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

Integer

(FEAT_MTE2)



Encoding

```
STGM <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE2) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
if !IsGMEnabledAtEL0() && PSTATE.EL == EL0 then Undefined(); end;

let data : bits(64) = X{64}(t);
var address : bits(64);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let size : integer{} = 4 * 2 ^ UInt(GMID_EL1().BS);

STILP

Store-release ordered pair of registers

This instruction calculates an address from a base register value and an optional offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The instruction also has memory ordering semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, with the additional requirement that:

- When using the pre-index addressing mode, the Memory effects associated with Xt2/Wt2 are Ordered-before the Memory effects associated with Xt1/Wt1.
- For all other addressing modes, the Memory effects associated with Xt1/Wt1 are Ordered-before the Memory effects associated with Xt2/Wt2.

For information about addressing modes, see *Load/Store addressing modes*.

Integer

(FEAT_LRCPC3)

```

Encoding for the 32-bit variant

Applies when `(size == 10 && opc2 == 0001)`

```
STILP <Wt1>, <Wt2>, [<Xn|SP>]
```

Encoding for the 64-bit pre-index variant

Applies when `(size == 11 && opc2 == 0000)`

```
STILP <Xt1>, <Xt2>, [<Xn|SP>, #-16]!
```

Encoding for the 64-bit variant

Applies when `(size == 11 && opc2 == 0001)`

```
STILP <Xt1>, <Xt2>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC3) then EndOfDecode(Decode_UNDEF); end;
let ispair : boolean = TRUE;
let wback : boolean = opc2[0] == '0';
```

STILP has the same CONSTRAINED UNPREDICTABLE behavior as STP. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STP and STILP*.

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

STL64B

Single-copy atomic 64-byte store-release without status result

This instruction stores eight 64-bit doublewords from consecutive registers to a memory location. The store starts at register Xt, with the data being formed as Data[511:0] = X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt. The data is stored atomically and is required to be 64-byte aligned.

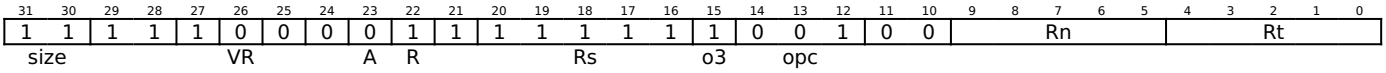
It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports STL64B also supports LD64B, LDA64B, and ST64B.

STL64B stores to memory with release semantics.

For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

Integer

(FEAT_LS64 && FEAT_LSC64B)



Encoding

```
STL64B <Xt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSC64B) then EndOfDecode(Decode_UNDEF); end;
if !IsFeatureImplemented(FEAT_LS64) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = FALSE;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = TRUE;
```

STL64B has the same CONSTRAINED UNPREDICTABLE behavior as ST64B. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *ST64B*.

Assembler Symbols

<Xt>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
CheckLDST64BEnabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_STORE, withstatus, acqrel, tagchecked);

for i = 0 to 7 do
    value = X{64}(t+i);
    if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;
    data[63+64*i : 64*i] = value;
end;

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

MemStore64B(address, data, accdesc);
```

STL64BV

Single-copy atomic 64-byte store-release with status result

This instruction stores eight 64-bit doublewords from consecutive registers to a memory location, and writes the status result of the store to a register. The store starts at register Xt, with the data being formed as Data[511:0] = X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt. The data is stored atomically and is required to be 64-byte aligned.

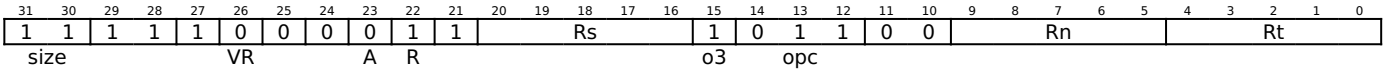
It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `STL64BV` also supports `ST64BV`, `ST64BV0`, and `STL64BV0`.

`STL64BV` stores to memory with release semantics.

For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

Integer

(FEAT_LS64_V && FEAT_LSC64B)



Encoding

```
STL64BV <Xs>, <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSC64B) then EndOfDecode(Decode_UNDEF); end;
if !IsFeatureImplemented(FEAT_LS64_V) then EndOfDecode(Decode_UNDEF); end;
if Rt[4:3] == '11' || Rt[0] == '1' then EndOfDecode(Decode_UNDEF); end;
let withstatus : boolean = TRUE;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let tagchecked : boolean = n != 31;
let acqrel : boolean = TRUE;
```

Assembler Symbols

<Xs> Is the 64-bit name of the general-purpose register into which the status result of this instruction is written, encoded in the "Rs" field. The value returned is:

0xFFFFFFFFFFFFFFFF
: If the memory location accessed does not support this instruction. In this case, the value at the memory location is UNKNOWN.

!= 0xFFFFFFFFFFFFFFFF
: If the memory location accessed does support this instruction. In this case, the peripheral that provides the response defines the returned value and provides information on the state of the memory update at the memory location.

If XZR is used, then the return value is ignored.

<Xt> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
CheckST64BVEnabled(acqrel);

var data : bits(512);
var address : bits(64);
var value : bits(64);

let accdesc : AccessDescriptor = CreateAccDescLS64(MemOp_STORE, withstatus, acqrel, tagchecked);

for i = 0 to 7 do
    value = X{64}(t+i);
    if BigEndian(accdesc.acctype) then value = BigEndianReverse{64}(value); end;
    data[63+64*i : 64*i] = value;
end;

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let status : bits(64) = MemStore64BWithRet(address, data, accdesc);

if s != 31 then X{64}(s) = status; end;
```

STL64BV0

Single-copy atomic 64-byte EL0 store-release with status result

This instruction stores eight 64-bit doublewords from consecutive registers to a memory location, with the bottom 32 bits taken from ACCDATA_EL1, and writes the status result of the store to a register. The store starts at register Xt, with the data being formed as Data[511:0] = X(t+7)::X(t+6)::X(t+5)::X(t+4)::X(t+3)::X(t+2)::X(t+1)::Xt[63:32]::ACCDATA_EL1()[31:0]. The data is stored atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `STL64BV0` also supports `ST64BV`, `ST64BV0`, and `STL64BV`.

`STL64BV0` stores to memory with release semantics.

For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

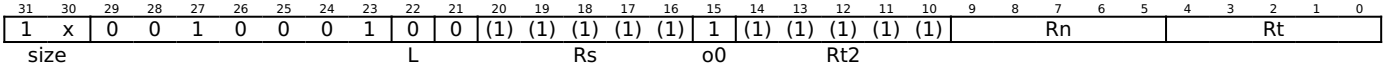
STLR

Store-release register

This instruction stores a 32-bit word or a 64-bit doubleword to a memory location, from a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 2 classes: No offset and Pre-index

No offset



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STLR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STLR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let wback : boolean = FALSE;

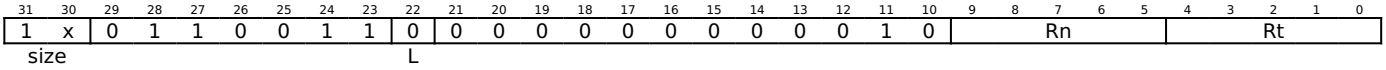
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 8 << UInt(size);
let offset : integer = 0;
let acquire : boolean = FALSE;
let tagchecked : boolean = n != 31;

let rt_unknown : boolean = FALSE;
```

Pre-index

(FEAT_LRCPC3)



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STLR <Wt>, [<Xn|SP>, #-4]!
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STLR <Xt>, [<Xn|SP>, #-8]!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC3) then EndOfDecode(Decode_UNDEF); end;
let wback : boolean = TRUE;

let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 8 << UInt(size);
let offset : integer = -1 * (1 << UInt(size));
let acquire : boolean = FALSE;
let tagchecked : boolean = TRUE;

var rt_unknown : boolean = FALSE;

if n == t && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE =>    rt_unknown = FALSE;   // value stored is original value
        when Constraint_UNKNOWN => rt_unknown = TRUE;    // value stored is UNKNOWN
        when Constraint_UNDEF =>   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>     EndOfDecode(Decode_NOP);
    end;
end;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

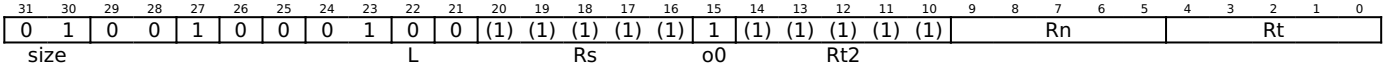
STLRH

Store-release register halfword

This instruction stores a halfword from a 32-bit register to a memory location. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STLRH <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_STORE, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

Mem{16}(address, accdesc) = X{16}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STLTXR

Store-release unprivileged exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

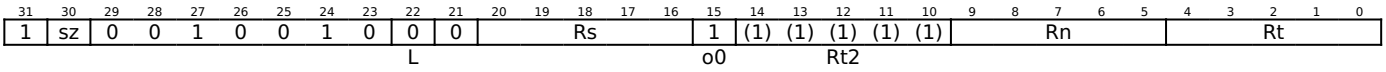
Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `STLTXR` is equivalent to `STXR`.

For information about addressing modes, see *Load/Store addressing modes*.

No offset

(FEAT_LSUI)



Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
STLTXR <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
STLTXR <Ws>, <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // store UNKNOWN value
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rn_unknown = TRUE;     // address is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

`STLTXR` has the same CONSTRAINED UNPREDICTABLE behavior as `STLXR`. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXR*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64_ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(elsize);
else
    data = X{elsize}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{elsize}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STLUR

Store-release register (unscaled)

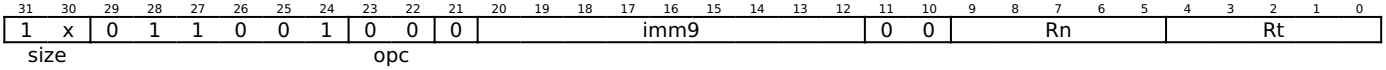
This instruction calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STLUR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STLUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);

let datasize : integer{} = 8 << scale;
let acquire : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_STORE, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STLURB

Store-release register byte (unscaled)

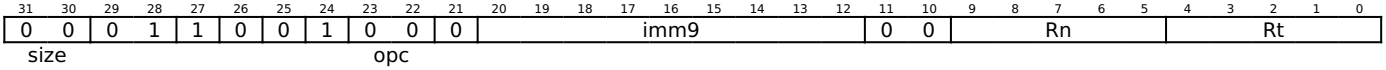
This instruction calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding

```
STLURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm9);
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);

let datasize : integer{} = 8;
let acquire : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_STORE, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STLURH

Store-release register halfword (unscaled)

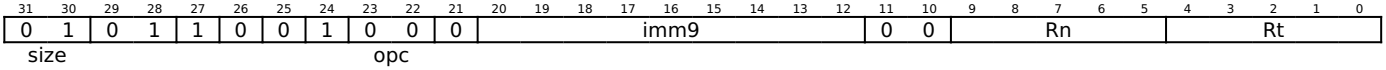
This instruction calculates an address from a base register value and an immediate offset, and stores a halfword to the calculated address, from a 32-bit register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*

For information about addressing modes, see *Load/Store addressing modes*.

Unscaled offset

(FEAT_LRCPC2)



Encoding

```
STLURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF); end;
let offset : bits(64) = SignExtend{}(imm9);
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);

let datasize : integer{} = 16;
let acquire : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Operation

```
var address : bits(64);

let accdesc : AccessDescriptor = CreateAccDescAcqRel(MemOp_STORE, tagchecked, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

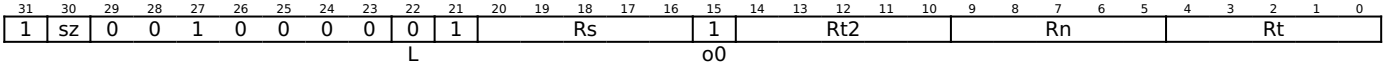
STLXP

Store-release exclusive pair of registers

This instruction stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics, as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
STLXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
STLXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let datasize : integer{} = elsize * 2;
let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t || s == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs* and *STLXP*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64_ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(datasize);

let dbytes : integer{} = datasize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
let ispair : boolean = FALSE;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, ispair, t, t2);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(datasize);
else
    let el1 : bits(datasize DIV 2) = X{}(t);
    let el2 : bits(datasize DIV 2) = X{}(t2);
    data = if BigEndian(accdesc.acctype) then el1::el2 else el2::el1;
end;
var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{datasize}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

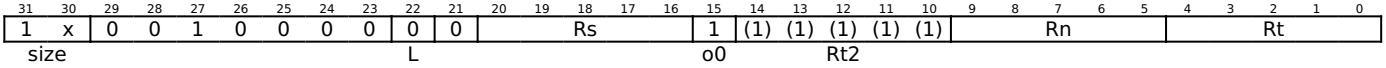
STLXR

Store-release exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STLXR <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STLXR <Ws>, <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 8 << UInt(size);
let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // store UNKNOWN value
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rn_unknown = TRUE;     // address is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXR*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0

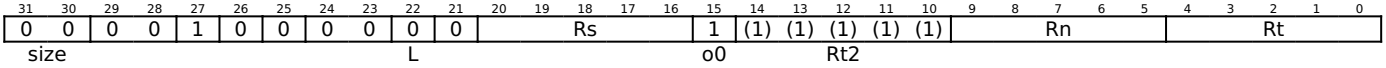
STLXRB

Store-release exclusive register byte

This instruction stores a byte from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STLXRB <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // store UNKNOWN value
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rn_unknown = TRUE;     // address is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXRB*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(8);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(8);
else
    data = X{8}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, 1, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{8}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

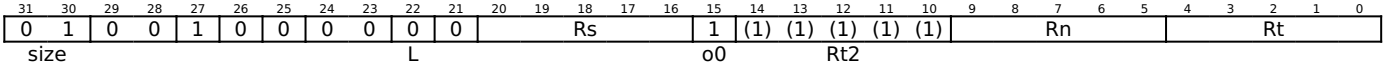
STLXRH

Store-release exclusive register halfword

This instruction stores a halfword from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STLXRH <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = TRUE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // store UNKNOWN value
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rn_unknown = TRUE;     // address is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXRH*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64_ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(16);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(16);
else
    data = X{16}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, 2, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{16}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

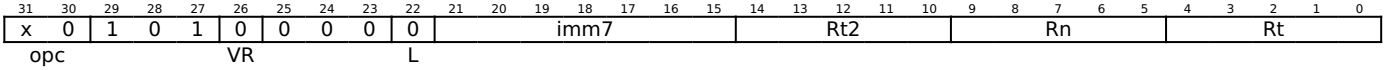
STNP

Store pair of registers, with non-temporal hint

This instruction calculates an address from a base register value and an immediate offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information about addressing modes, see *Load/Store addressing modes*. For information about non-temporal pair instructions, see *Load/Store non-temporal pair*.



Encoding for the 32-bit variant

Applies when `(opc == 00)`

```
STNP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
STNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = TRUE;
let scale : integer{} = 2 + UInt(opc[1]);
let datasize : integer{} = 8 << scale;
let offset : bits(64) = LSL(SignExtend{64}(imm7), scale);
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the "32-bit" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. For the "64-bit" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Operation

```
var address : bits(64);
let privileged : boolean = PSTATE.EL != EL0;
let ispair : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, ispair, t, t2);
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);
let data : bits(2*datasize) = (if BigEndian(accdesc.acctype)
                                 then X{datasize}(t) :: X{datasize}(t2)
                                 else X{datasize}(t2) :: X{datasize}(t));
Mem{2*datasize}(address, accdesc) = data;
```

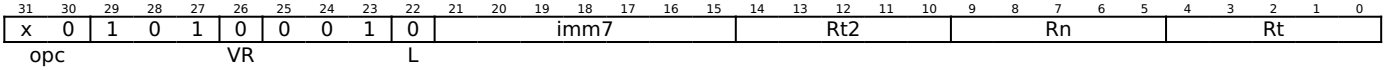
STP

Store pair of registers

This instruction calculates an address from a base register value and an immediate offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index



Encoding for the 32-bit variant

Applies when `(opc == 00)`

```
STP <Wt1>, <Wt2>, [<Xn|SP>], #<imm>
```

Encoding for the 64-bit variant

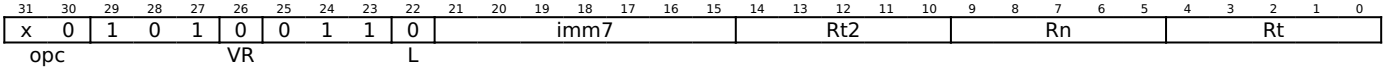
Applies when `(opc == 10)`

```
STP <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

Decode for all variants of this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = TRUE;
```

Pre-index



Encoding for the 32-bit variant

Applies when `(opc == 00)`

```
STP <Wt1>, <Wt2>, [<Xn|SP>, #<imm>]!
```

Encoding for the 64-bit variant

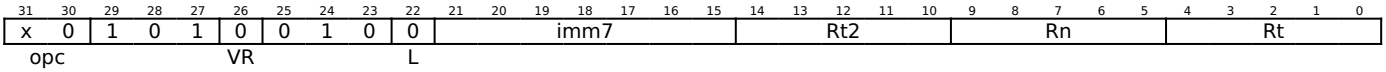
Applies when `(opc == 10)`

```
STP <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

Decode for all variants of this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = FALSE;
```

Signed offset



Encoding for the 32-bit variant

Applies when `(opc == 00)`

```
STP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant

Applies when `(opc == 10)`

```
STP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
let wback : boolean = FALSE;
let postindex : boolean = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STP*.

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the "Post-index 32-bit" and "Pre-index 32-bit" variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4. For the "Post-index 64-bit" and "Pre-index 64-bit" variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8. For the "Signed offset 32-bit" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. STR (immediate)

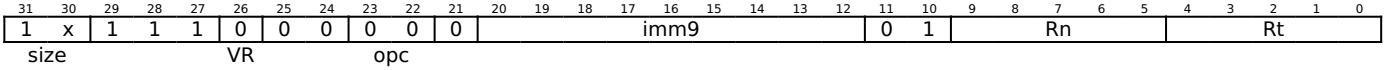
Store register (immediate)

This instruction stores a word or a doubleword from a register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STR <Wt>, [<Xn|SP>], #<simm>
```

Encoding for the 64-bit variant

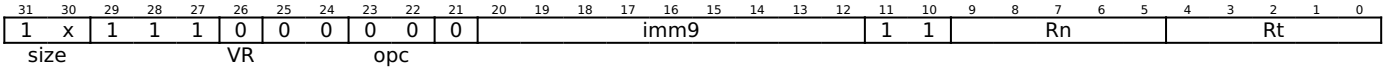
Applies when `(size == 11)`

```
STR <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = TRUE;
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STR <Wt>, [<Xn|SP>, #<simm>]!
```

Encoding for the 64-bit variant

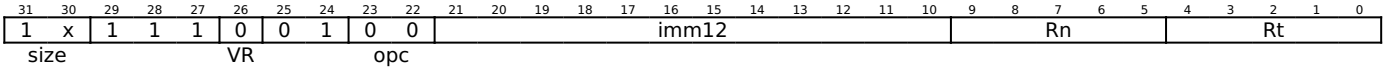
Applies when `(size == 11)`

```
STR <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = FALSE;
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STR <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STR <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
let wback : boolean = FALSE;
let postindex : boolean = FALSE;
let scale : integer{} = UInt(size);
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), scale);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<pimm>	For the "32-bit" variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4. For the "64-bit" variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 8 << scale;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var rt_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);

    case c of
        when Constraint_NONE =>    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN => rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF =>   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>     EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

var data : bits(datasize);
if rt_unknown then
    data = ARBITRARY : bits(datasize);
else
    data = X{datasize}(t);
end;

Mem{datasize}(address, accdesc) = data;

if wback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

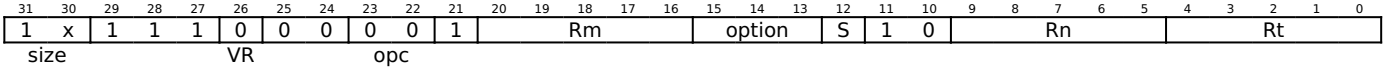
STR (register)

Store register (register)

This instruction calculates an address from a base register value and an offset register value, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about addressing modes, see *Load/Store addressing modes*.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STR <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let scale : integer{} = UInt(size);
let shift : integer{} = if S == '1' then scale else 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> For the "32-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#2

For the "64-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#3

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 8 << scale;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

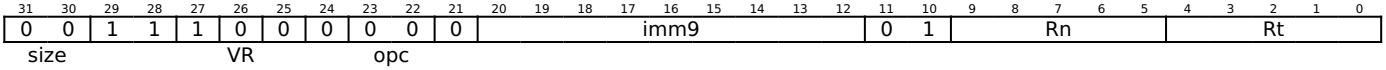
STRB (immediate)

Store register byte (immediate)

This instruction stores the least significant byte of a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



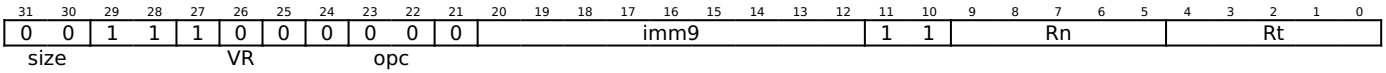
Encoding

```
STRB <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



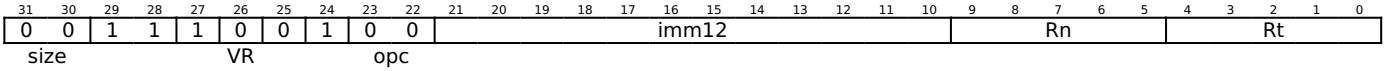
Encoding

```
STRB <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding

```
STRB <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
let wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 0);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRB (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var rt_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE =>    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN => rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF =>   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>     EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

var data : bits(8);
if rt_unknown then
    data = ARBITRARY : bits(8);
else
    data = X{8}(t);
end;

Mem{8}(address, accdesc) = data;

if wback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

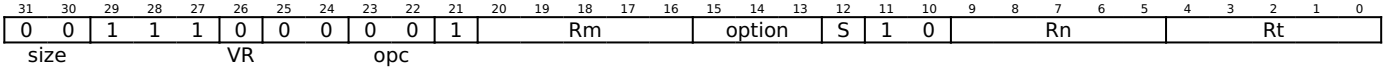
STRB (register)

Store register byte (register)

This instruction calculates an address from a base register value and an offset register value, and stores a byte from a 32-bit register to the calculated address. For information about addressing modes, see *Load/Store addressing modes*.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



Encoding for the Extended register variant

Applies when `(option != 011)`

```
STRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the Shifted register variant

Applies when `(option == 011)`

```
STRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW
110	SXTW
111	SXTX

<amount> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{8}(address, accdesc) = X{8}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

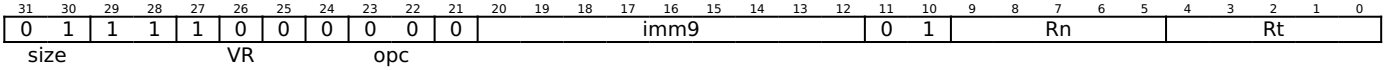
STRH (immediate)

Store register halfword (immediate)

This instruction stores the least significant halfword of a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



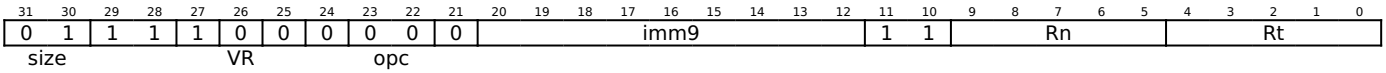
Encoding

```
STRH <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = TRUE;
let offset : bits(64) = SignExtend{}(imm9);
```

Pre-index



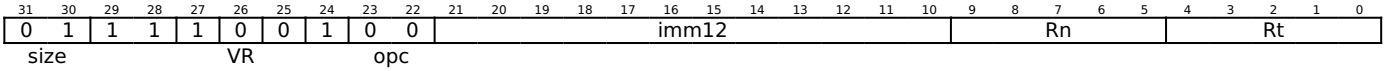
Encoding

```
STRH <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
let wback : boolean = TRUE;
let postindex : boolean = FALSE;
let offset : bits(64) = SignExtend{}(imm9);
```

Unsigned offset



Encoding

```
STRH <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
let wback : boolean = FALSE;
let postindex : boolean = FALSE;
let offset : bits(64) = LSL(ZeroExtend{64}(imm12), 1);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRH (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

var c : Constraint;
var rt_unknown : boolean = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE =>    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN => rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF =>   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>     EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

var data : bits(16);
if rt_unknown then
    data = ARBITRARY : bits(16);
else
    data = X{16}(t);
end;

Mem{16}(address, accdesc) = data;

if wback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

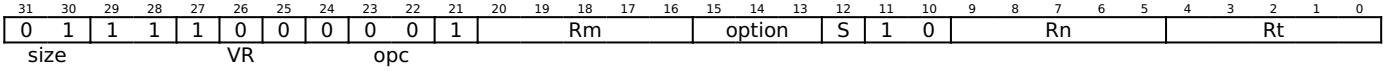
STRH (register)

Store register halfword (register)

This instruction calculates an address from a base register value and an offset register value, and stores a halfword from a 32-bit register to the calculated address. For information about addressing modes, see *Load/Store addressing modes*.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



Encoding

```
STRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option[1] == '0' then EndOfDecode(Decode_UNDEF); end;          // sub-word index
let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#1

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
```

Operation

```
let offset : bits(64) = ExtendReg{}(m, extend_type, shift);
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{16}(address, accdesc) = X{16}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STSET, STSETL

Atomic bit set on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STSET` does not have release semantics.
- `STSETL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

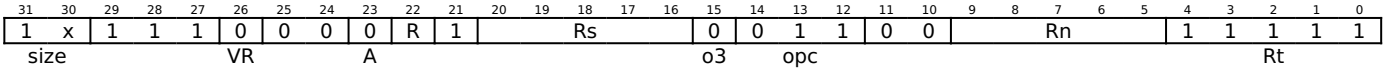
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDSET, LDSETA, LDSETAL, LDSETL. This means:

- The encodings in this description are named to match the encodings of LDSET, LDSETA, LDSETAL, LDSETL.
- The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && R == 0)`

```
STSET <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSET <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant

Applies when `(size == 10 && R == 1)`

```
STSETL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && R == 0)`

```
STSET <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSET <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant

Applies when `(size == 11 && R == 1)`

```
STSETL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSETL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

Operation

The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this instruction.

Operational Information

The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational information for this instruction.

STSETB, STSETLB

Atomic bit set on byte, without return

This instruction atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STSETB` does not have release semantics.
- `STSETLB` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

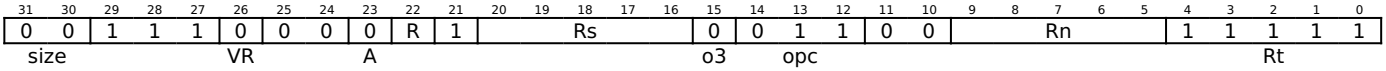
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB. This means:

- The encodings in this description are named to match the encodings of LDSETB, LDSETAB, LDSETALB, LDSETLB.
- The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(R == 0)`

```
STSETB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the Release variant

Applies when `(R == 1)`

```
STSETLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.

Operational Information

The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational information for this instruction.

STSETH, STSETLH

Atomic bit set on halfword, without return

This instruction atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STSETH` does not have release semantics.
- `STSETLH` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

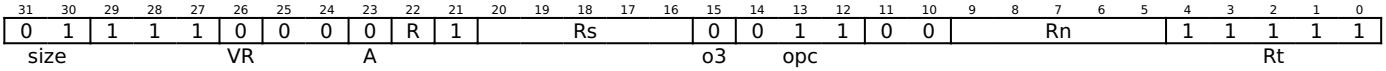
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDSETH, LDSETAH, LDSETALH, LDSETLH. This means:

- The encodings in this description are named to match the encodings of LDSETH, LDSETAH, LDSETALH, LDSETLH.
- The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(R == 0)`

```
STSETH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the Release variant

Applies when `(R == 1)`

```
STSETLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode for this instruction.

Operational Information

The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational information for this instruction.

STSHH

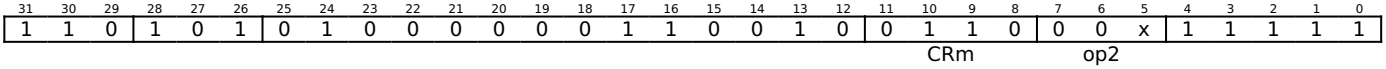
Store shared hint

This instruction signals to the memory system that if the next instruction in program order generates an explicit write effect, then it is to a location that one or more other threads of execution will observe, and there is a performance benefit to ensuring that the updated value from the write to that location propagates to those other observers with minimal latency.

The thread of execution on the other observers might be polling the location using load or Load-Exclusive instructions, or may have executed a `PRFM IR` instruction targeting the location.

System

(FEAT_PCDPHINT)



Encoding

`STSHH` <policy>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PCDPHINT) then EndOfDecode(Decode_NOP); end;
let stream : boolean = op2[0] == '1';
```

Assembler Symbols

<policy> <policy> is one of:

KEEP
: Signals to the memory system that there may be a performance benefit to retaining the updated location in the local cache of the updating PE.

STRM
: Signals to the memory system that there may be a performance benefit to ensuring the updated location is not retained in the local cache of the updating PE.

op2[0]	<policy>
0	KEEP
1	STRM

Operation

```
Hint_StoreShared(stream);
```

STSMAX, STSMAXL

Atomic signed maximum on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- `STSMAX` does not have release semantics.
- `STSMAXL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

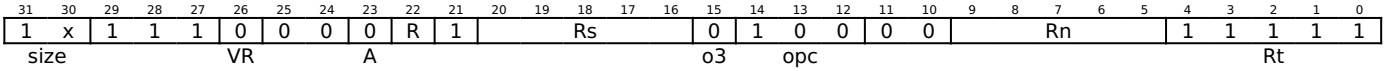
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL. This means:

- The encodings in this description are named to match the encodings of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.
- The description of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && R == 0)`

```
STSMAX <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAX <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant

Applies when `(size == 10 && R == 1)`

```
STSMAXL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && R == 0)`

```
STSMAX <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSMAX <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant

Applies when `(size == 11 && R == 1)`

```
STSMAXL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

STSMAXH, STSMAXLH

Atomic signed maximum on halfword, without return

This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- `STSMAXH` does not have release semantics.
- `STSMAXLH` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

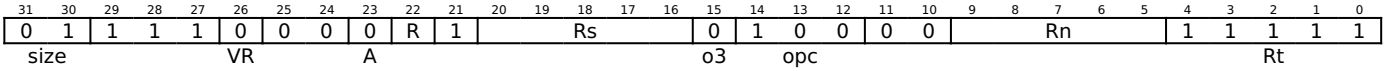
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH. This means:

- The encodings in this description are named to match the encodings of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.
- The description of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the No memory ordering variant

Applies when `(R == 0)`

```
STSMAXH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the Release variant

Applies when `(R == 1)`

```
STSMAXLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH gives the operational pseudocode for this instruction.

Operational Information

The description of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH gives the operational information for this instruction.

STSMIN, STSMINL

Atomic signed minimum on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

- `STSMIN` does not have release semantics.
- `STSMINL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

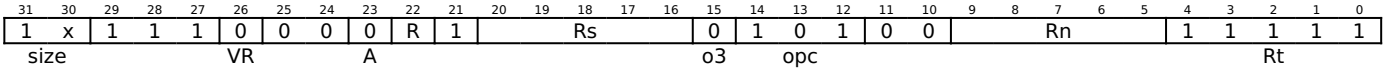
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDSMIN, LDSMINA, LDSMINAL, LDSMINL. This means:

- The encodings in this description are named to match the encodings of LDSMIN, LDSMINA, LDSMINAL, LDSMINL.
- The description of LDSMIN, LDSMINA, LDSMINAL, LDSMINL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && R == 0)`

```
STSMIN <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMIN <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant

Applies when `(size == 10 && R == 1)`

```
STSMINL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMINL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && R == 0)`

```
STSMIN <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSMIN <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant

Applies when `(size == 11 && R == 1)`

```
STSMINL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSMINL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

STTADD, STTADDL

Atomic add unprivileged, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory.

- `STTADD` does not have release semantics.
- `STTADDL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDTADD, LDTADDA, LDTADDAL, LDTADDL. This means:

- The encodings in this description are named to match the encodings of LDTADD, LDTADDA, LDTADDAL, LDTADDL.

STTCLR, STTCLRL

Atomic bit clear unprivileged, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

- `STTCLR` does not have release semantics.
- `STTCLRL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL. This means:

- The encodings in this description are named to match the encodings of LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL.

STTNP

Store unprivileged pair of registers, with non-temporal hint

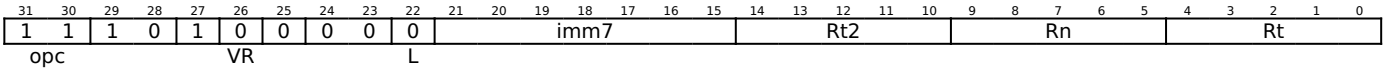
This instruction calculates an address from a base register value and an immediate offset, and stores two 64-bit doublewords to the calculated address, from two registers. For information about addressing modes, see *Load/Store addressing modes*. For information about non-temporal pair instructions, see *Load/Store non-temporal pair*.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Signed offset

(FEAT_LSUI)



Encoding

```
STTNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = TRUE;
let datasize : integer{} = 64;
let offset : bits(64) = LSL(SignExtend{64}(imm7), 3);
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	Is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Operation

```
var address : bits(64);
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let ispair : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, ispair, t, t2);
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);
let data : bits(2*datasize) = (if BigEndian(accdesc.acctype)
                                 then X{datasize}(t) :: X{datasize}(t2)
                                 else X{datasize}(t2) :: X{datasize}(t));
Mem{2*datasize}(address, accdesc) = data;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

STTP

Store unprivileged pair of registers

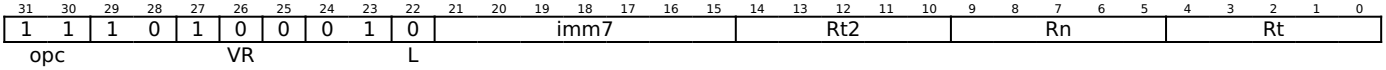
This instruction calculates an address from a base register value and an immediate offset, and stores two 64-bit doublewords to the calculated address, from two registers.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.
For information about addressing modes, see *Load/Store addressing modes*.
It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index

(FEAT_LSUI)



Encoding

```
STTP <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

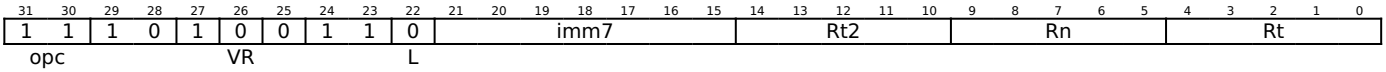
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

let wback : boolean = TRUE;
let postindex : boolean = TRUE;
```

Pre-index

(FEAT_LSUI)



Encoding

```
STTP <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

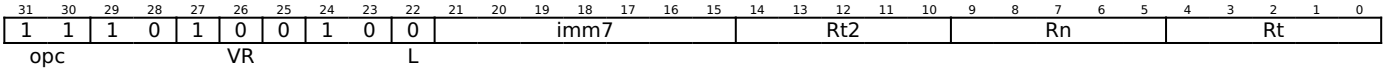
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

let wback : boolean = TRUE;
let postindex : boolean = FALSE;
```

Signed offset

(FEAT_LSUI)



Encoding

```
STTP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

let wback : boolean = FALSE;
let postindex : boolean = FALSE;
```

STTP has the same CONSTRAINED UNPREDICTABLE behavior as STP. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STP*.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the "Post-index" and "Pre-index" variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8. For the "Signed offset" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Shared Decode

```
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let nontemporal : boolean = FALSE;
let scale : integer{} = 2 + UInt(opc[1]);
let datasize : integer{} = 64;
let offset : bits(64) = LSL(SignExtend{64}(imm7), scale);
let tagchecked : boolean = wback || n != 31;

var rt_unknown : boolean = FALSE;

if wback && (t == n || t2 == n) && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE =>       rt_unknown = FALSE;   // Value stored is pre-writeback
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // Value stored is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

Operation

```
var address : bits(64);
var data1 : bits(datasize);
var data2 : bits(datasize);
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let ispair : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, ispair, t, t2);
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

if rt_unknown && t == n then
    data1 = ARBITRARY : bits(datasize);
else
    data1 = X{datasize}(t);
end;
if rt_unknown && t2 == n then
    data2 = ARBITRARY : bits(datasize);
else
    data2 = X{datasize}(t2);
end;

let data : bits(2*datasize) = (if BigEndian(accdesc.acctype) then data1::data2
                                                             else data2::data1);
Mem{2 * datasize}(address, accdesc) = data;

if wback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    end;
    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

STTR

Store register (unprivileged)

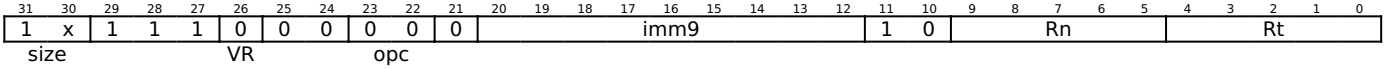
This instruction stores a word or doubleword from a register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STTR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STTR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 8 << scale;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STTRB

Store register byte (unprivileged)

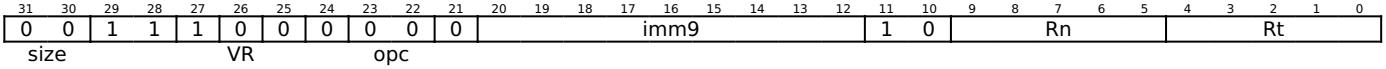
This instruction stores a byte from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STTRB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 8;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STTRH

Store register halfword (unprivileged)

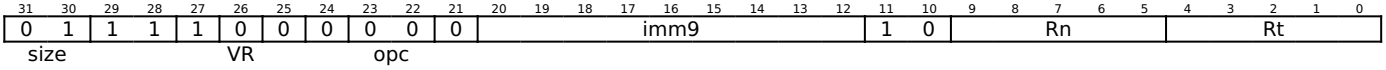
This instruction stores a halfword from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STTRH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let datasize : integer{} = 16;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STTSET, STTSETL

Atomic bit set unprivileged, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STTSET` does not have release semantics.
- `STTSETL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

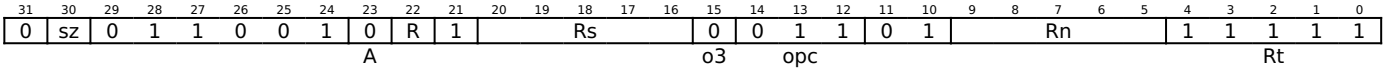
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDTSET, LDTSETA, LDTSETAL, LDTSETL. This means:

- The encodings in this description are named to match the encodings of LDTSET, LDTSETA, LDTSETAL, LDTSETL.
- The description of LDTSET, LDTSETA, LDTSETAL, LDTSETL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSUI)



Encoding for the 32-bit no memory ordering variant

Applies when `(sz == 0 && R == 0)`

```
STTSET <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDTSET <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant

Applies when `(sz == 0 && R == 1)`

```
STTSETL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDTSETL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant

Applies when `(sz == 1 && R == 0)`

```
STTSET <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDTSET <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant

Applies when `(sz == 1 && R == 1)`

```
STTSETL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDTSETL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

Operation

The description of LDTSET, LDTSETA, LDTSETAL, LDTSETL gives the operational pseudocode for this instruction.

Operational Information

The description of LDTSET, LDTSETA, LDTSETAL, LDTSETL gives the operational information for this instruction.

STTXR

Store unprivileged exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*.
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

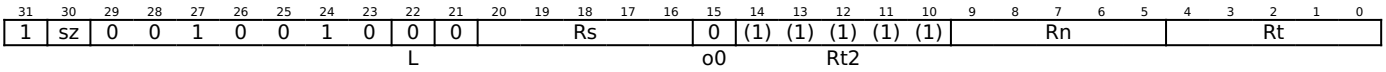
Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, STTXR is equivalent to STXR.

For information about addressing modes, see *Load/Store addressing modes*.

No offset

(FEAT_LSUI)



Encoding for the 32-bit variant

Applies when (sz == 0)

```
STTXR <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when (sz == 1)

```
STTXR <Ws>, <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

STTXR has the same CONSTRAINED UNPREDICTABLE behavior as STXR. For information about this CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXR*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64_ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(elsize);
else
    data = X{elsize}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{elsize}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STUMAX, STUMAXL

Atomic unsigned maximum on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- STUMAX does not have release semantics.
- STUMAXL stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

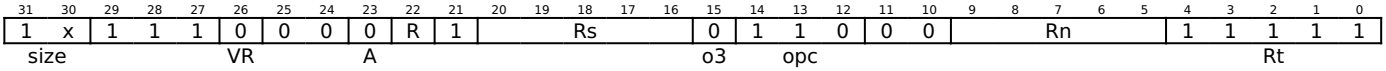
For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL. This means:

- The encodings in this description are named to match the encodings of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.
- The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant

Applies when `(size == 10 && R == 0)`

```
STUMAX <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAX <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant

Applies when `(size == 10 && R == 1)`

```
STUMAXL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant

Applies when `(size == 11 && R == 0)`

```
STUMAX <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDUMAX <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant

Applies when `(size == 11 && R == 1)`

```
STUMAXL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

Operation

The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

Operational Information

The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational information for this instruction.

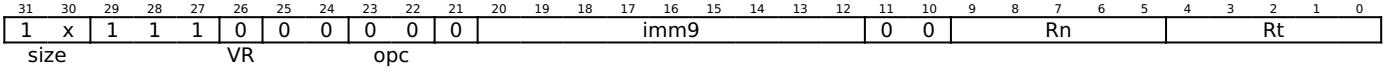
STUR

Store register (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STUR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
let scale : integer{} = UInt(size);
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 8 << scale;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

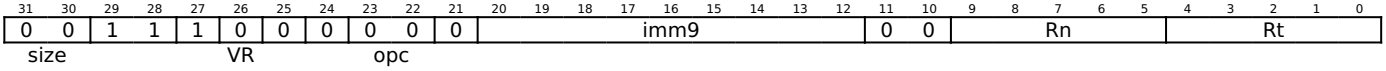
STURB

Store register byte (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 8;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

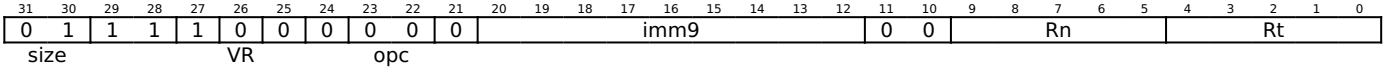
STURH

Store register halfword (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a halfword to the calculated address, from a 32-bit register. For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
let offset : bits(64) = SignExtend{}(imm9);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
let n : integer = UInt(Rn);
let t : integer = UInt(Rt);
let datasize : integer{} = 16;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                  tagchecked, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = X{datasize}(t);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STXP

Store exclusive pair of registers

This instruction stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about addressing modes, see *Load/Store addressing modes*.

Encoding for the 32-bit variant

Applies when `(sz == 0)`

```
STXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(sz == 1)`

```
STXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 32 << UInt(sz);
let datasize : integer{} = elsize * 2;
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t || s == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF =>      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>        EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs* and *STXP*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64_ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(datasize);

let dbytes : integer{} = datasize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
let ispair : boolean = FALSE;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, ispair, t, t2);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(datasize);
else
    let el1 : bits(datasize DIV 2) = X{}(t);
    let el2 : bits(datasize DIV 2) = X{}(t2);
    data = if BigEndian(accdesc.acctype) then el1::el2 else el2::el1;
end;
var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{datasize}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

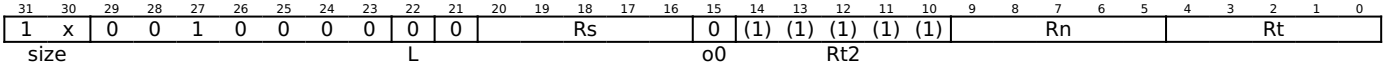
STXR

Store exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding for the 32-bit variant

Applies when `(size == 10)`

```
STXR <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant

Applies when `(size == 11)`

```
STXR <Ws>, <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let elsize : integer{} = 8 << UInt(size);
let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // store UNKNOWN value
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rn_unknown = TRUE;     // address is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXR*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64_ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(elsize);

let dbytes : integer{} = elsize DIV 8;
let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(elsize);
else
    data = X{elsize}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{elsize}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

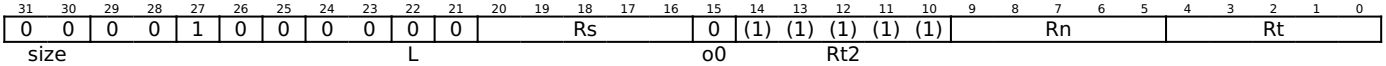
STXRB

Store exclusive register byte

This instruction stores a byte from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STXRB <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // store UNKNOWN value
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rn_unknown = TRUE;     // address is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXRB*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(8);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(8);
else
    data = X{8}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, 1, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{8}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

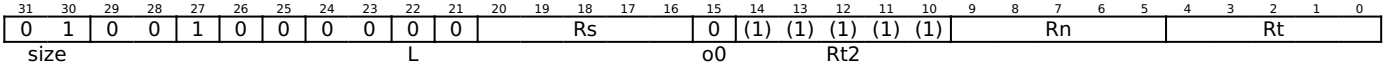
STXRH

Store exclusive register halfword

This instruction stores a halfword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic.

For information about addressing modes, see *Load/Store addressing modes*.



Encoding

```
STXRH <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acqrel : boolean = FALSE;
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;
var rn_unknown : boolean = FALSE;
if s == t then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // store UNKNOWN value
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
if s == n && n != 31 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rn_unknown = TRUE;     // address is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXRH*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort or Watchpoint exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64_ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort or Watchpoint exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
var address : bits(64);
var data : bits(16);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescExLDST(MemOp_STORE, acqrel, tagchecked,
                                                     privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
elsif rn_unknown then
    address = ARBITRARY : bits(64);
else
    address = X{64}(n);
end;

if rt_unknown then
    data = ARBITRARY : bits(16);
else
    data = X{16}(t);
end;

var status : bit = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64_ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort or Watchpoint exception,
// it is IMPLEMENTATION DEFINED whether the exception is generated.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64_ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64_ExclusiveMonitorsPass(address, 2, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem{16}(address, accdesc) = data;
    status = ExclusiveMonitorsStatus();
end;
X{32}(s) = ZeroExtend{32}(status);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

STZ2G

Store Allocation Tags, zeroing

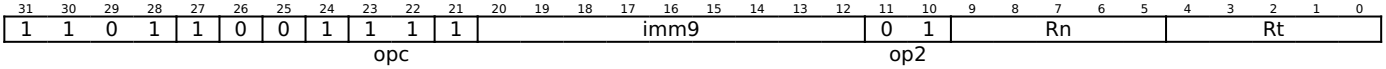
This instruction stores an Allocation Tag to two Tag Granules of memory, zeroing the associated data locations. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag Granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index

(FEAT_MTE)



Encoding

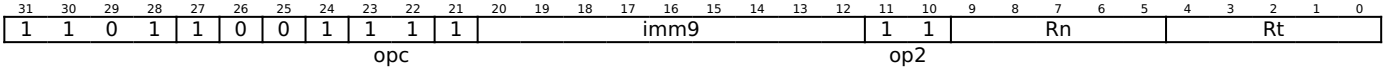
```
STZ2G <Xt|SP>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = TRUE;
let postindex : boolean = TRUE;
```

Pre-index

(FEAT_MTE)



Encoding

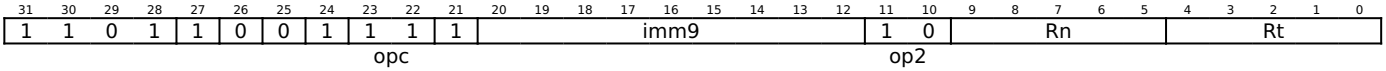
```
STZ2G <Xt|SP>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = TRUE;
let postindex : boolean = FALSE;
```

Signed offset

(FEAT_MTE)



Encoding

```
STZ2G <Xt|SP>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let offset : bits(64) = LSL(SignExtend{64}(imm9), LOG2_TAG_GRANULE);
let writeback : boolean = FALSE;
let postindex : boolean = FALSE;
```

Assembler Symbols

<Xt|SP>	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate offset, a multiple of 16 in the range -4096 to 4080, defaulting to 0 and encoded in the "imm9" field.

Operation

```
var address : bits(64);
var address2 : bits(64);
let data : bits(64) = if t == 31 then SP{64}() else X{64}(t);
let tag : bits(4) = AArch64_AllocationTagFromAddress(data);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let stzgm : boolean = FALSE;
let ispair : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescLDGSTG(MemOp_STORE, stzgm, ispair, t, t);

if !postindex then
    address = AddressAdd(address, offset, accdesc);
end;

address2 = AddressIncrement(address, TAG_GRANULE, accdesc);

if !IsAlignedSize(address, TAG_GRANULE) then
    let fault : FaultRecord = AlignmentFault(accdesc, address);
    AArch64_Abort(fault);
end;

Mem{16*TAG_GRANULE}(address, accdesc) = Zeros{TAG_GRANULE * 16};

AArch64_MemTag(address, accdesc) = tag;
AArch64_MemTag(address2, accdesc) = tag;

if writeback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    end;

    if n == 31 then
        SP{64}() = address;
    else
        X{64}(n) = address;
    end;
end;
```

STZGM

Store Allocation Tag and zero multiple

This instruction writes a naturally aligned block of N Allocation Tags and stores zero to the associated data locations, where the size of N is identified in DCZID_EL0.BS, and the Allocation Tag is taken from the source register bits<3:0>.

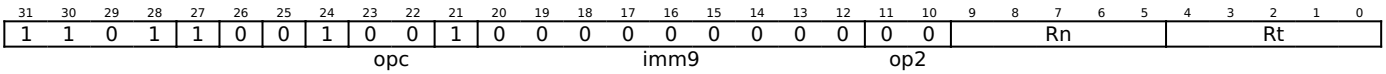
If the value of HCR_EL2.TGE is 0 and the Effective value of SCTLR2_EL1.GM0 is 0, this instruction is UNDEFINED at EL0.

If the value of HCR_EL2.TGE is 1 and the Effective value of SCTLR2_EL2.GM0 is 0, this instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

Integer

(FEAT_MTE2)



Encoding

```
STZGM <Xt>, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE2) then EndOfDecode(Decode_UNDEF); end;
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
if !IsGMEnabledAtEL0() && PSTATE.EL == EL0 then Undefined(); end;

let data : bits(64) = X{64}(t);
let tag : bits(4) = data[3:0];
var address : bits(64);
if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

let size : integer{} = 4 * 2 ^ UInt(DCZID_EL0().BS);
address = AlignDownSize(address, size);
let count : integer = size >> LOG2_TAG_GRANULE;
let stzgm : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescLDGSTG(MemOp_STORE, stzgm, t);

for i = 0 to count-1 do
    AArch64_MemTag(address, accdesc) = tag;
    Mem{8*TAG_GRANULE}(address, accdesc) = Zeros{8*TAG_GRANULE};
    address = AddressIncrement(address, TAG_GRANULE, accdesc);
end;
```

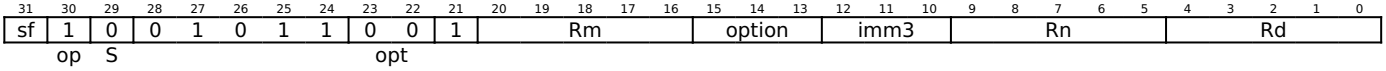
SUB (extended register)

Subtract extended and scaled register

This instruction subtracts a sign-extended or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUB <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUB <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer{} = UInt(imm3) as integer{0..4};
let datasize : integer{} = 32 << UInt(sf);
let extend_type : ExtendType = DecodeRegExtend(option);
```

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = NOT ExtendReg{datasize}(m, extend_type, shift);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '1');

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

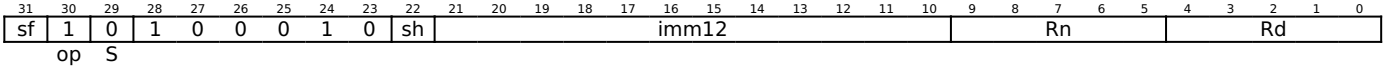
SUB (immediate)

Subtract immediate value

This instruction subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUB <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUB <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);

let imm : bits(24) = if sh == '0' then Zeros{12}::imm12 else imm12::Zeros{12};
```

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = NOT ZeroExtend{datasize}(imm);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '1');

if d == 31 then
    SP{64}() = ZeroExtend{64}(result);
else
    X{datasize}(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

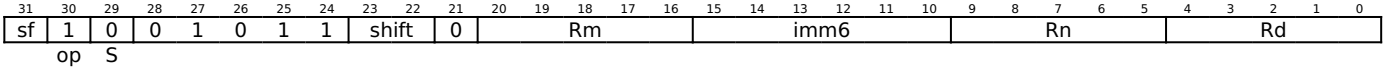
SUB (shifted register)

Subtract optionally-shifted register

This instruction subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.
This instruction is used by the alias NEG (shifted register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUB <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUB <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
NEG (shifted register)	`Rn == '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = NOT ShiftReg{datasize}(m, shift_type, shift_amount);

var result : bits(datasize);
(result, -) = AddWithCarry{datasize}(operand1, operand2, '1');

X{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

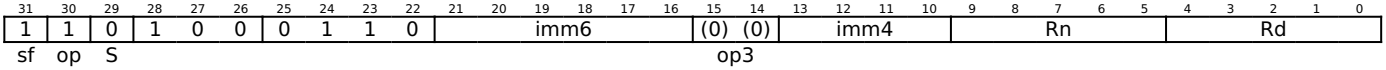
SUBG

Subtract with tag

This instruction subtracts an immediate value scaled by the Tag Granule from the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

Integer

(FEAT_MTE)



Encoding

```
SUBG <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let tag_offset : bits(4) = imm4;
let offset : bits(64) = LSL(ZeroExtend{64}(imm6), LOG2_TAG_GRANULE);
```

Assembler Symbols

<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<uimm6>	Is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the "imm6" field.
<uimm4>	Is an unsigned immediate, in the range 0 to 15, encoded in the "imm4" field.

Operation

```
let operand1 : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let start_tag : bits(4) = AArch64_AllocationTagFromAddress(operand1);
let exclude : bits(16) = GCR_EL1().Exclude;
let rtag : bits(4) = AArch64_ChooseNonExcludedTagOrZero(start_tag, tag_offset, exclude);
var result : bits(64);

(result, -) = AddWithCarry{64}(operand1, NOT offset, '1');

result = AArch64_AddressWithAllocationTag(result, rtag);

if d == 31 then
    SP{64}() = result;
else
    X{64}(d) = result;
end;
```

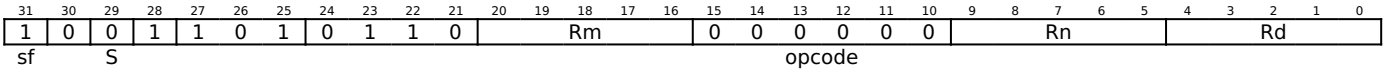
SUBP

Subtract pointer

This instruction subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, sign-extends the result to 64 bits, and writes the result to the destination register.

Integer

(FEAT_MTE)



Encoding

```
SUBP <Xd>, <Xn|SP>, <Xm|SP>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xm|SP>	Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Operation

```
var operand1 : bits(64) = if n == 31 then SP{64}() else X{64}(n);
var operand2 : bits(64) = if m == 31 then SP{64}() else X{64}(m);
operand1 = SignExtend{64}(operand1[55:0]);
operand2 = NOT SignExtend{64}(operand2[55:0]);
var result : bits(64);

(result, -) = AddWithCarry{64}(operand1, operand2, '1');

X{64}(d) = result;
```

SUBPS

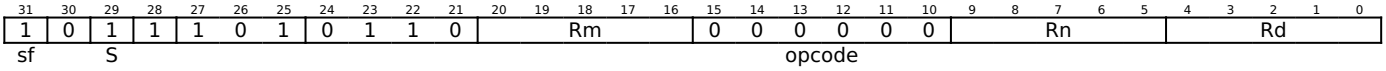
Subtract pointer, setting flags

This instruction subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, sign-extends the result to 64 bits, and writes the result to the destination register. It updates the condition flags based on the result of the subtraction.

This instruction is used by the alias CMPP.

Integer

(FEAT_MTE)



Encoding

```
SUBPS <Xd>, <Xn|SP>, <Xm|SP>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xm|SP>	Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CMPP	`S == '1' && Rd == '11111'`

Operation

```
var operand1 : bits(64) = if n == 31 then SP{64}() else X{64}(n);
var operand2 : bits(64) = if m == 31 then SP{64}() else X{64}(m);
operand1 = SignExtend{64}(operand1[55:0]);
operand2 = NOT SignExtend{64}(operand2[55:0]);
var result : bits(64);

var nzcv : bits(4);

(result, nzcv) = AddWithCarry{64}(operand1, operand2, '1');

X{64}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

SUBPT

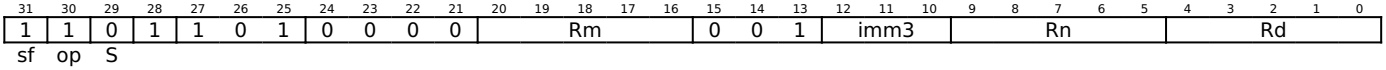
Subtract checked pointer

This instruction subtracts an optionally-shifted register value from a base address register value, and writes the result to the destination register. The optionally-shifted register value is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)



Encoding

```
SUBPT <Xd|SP>, <Xn|SP>, <Xm>{, LSL #<amount>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CPA) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer = UInt(imm3);
```

Assembler Symbols

<Xd|SP>	Is the 64-bit name of the general-purpose destination register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the first general-purpose source register or stack pointer, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<amount>	Is the left shift amount, in the range 0 to 7, defaulting to 0, encoded in the "imm3" field.

Operation

```
var result : bits(64);
let base : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let offset : bits(64) = LSL(X{64}(m), shift);

result = base - offset;
result = PointerAddCheck(result, base);

if d == 31 then
    SP{64}() = result;
else
    X{64}(d) = result;
end;
```

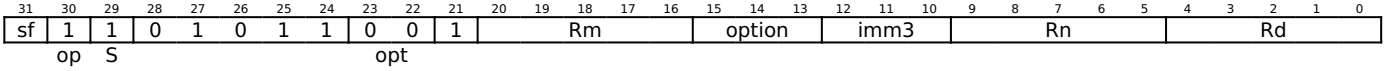
SUBS (extended register)

Subtract extended and scaled register, setting flags

This instruction subtracts a sign-extended or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMP (extended register).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let shift : integer{} = UInt(imm3) as integer{0..4};
let datasize : integer{} = 32 << UInt(sf);
let extend_type : ExtendType = DecodeRegExtend(option);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CMP (extended register)	`Rd == '11111'`

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = NOT ExtendReg{datasize}(m, extend_type, shift);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '1');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

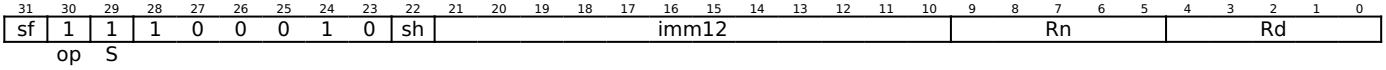
SUBS (immediate)

Subtract immediate value, setting flags

This instruction subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMP (immediate).



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUBS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUBS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);

let imm : bits(24) = if sh == '0' then Zeros{12}::imm12 else imm12::Zeros{12};
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
CMP (immediate)	`Rd == '11111'`

Operation

```
let operand1 : bits(datasize) = if n == 31 then SP{datasize}() else X{datasize}(n);
let operand2 : bits(datasize) = NOT ZeroExtend{datasize}(imm);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '1');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

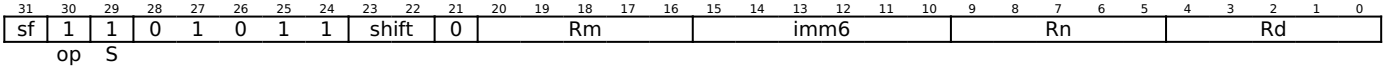
SUBS (shifted register)

Subtract optionally-shifted register, setting flags

This instruction subtracts an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the aliases CMP (shifted register), and NEGS.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
SUBS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
SUBS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && imm6[5] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
let shift_type : ShiftType = DecodeShift(shift);
let shift_amount : integer = UInt(imm6);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CMP (shifted register)	`Rd == '11111'`
NEGS	`Rn == '11111' && Rd != '11111'`

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = NOT ShiftReg{datasize}(m, shift_type, shift_amount);

var result : bits(datasize);
var nzcv : bits(4);

(result, nzcv) = AddWithCarry{datasize}(operand1, operand2, '1');

X{datasize}(d) = result;
PSTATE.[N,Z,C,V] = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

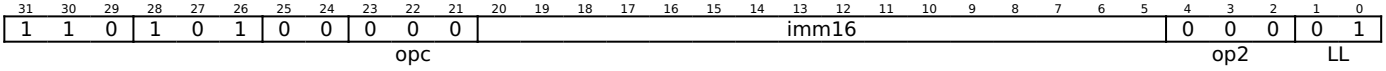
SVC

Supervisor call

This instruction causes an exception to be taken to EL1.
On executing an `SVC` instruction, the PE records the exception as a Supervisor Call exception in *ESR_ELx*, using the EC syndrome value 0x15, and the value of the immediate argument.



Encoding

```
SVC #<imm>
```

Decode for this encoding

```
let imm : bits(16) = imm16;
```

Assembler Symbols

<imm>	Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64_CheckForSVCTrap(imm);
AArch64_CallSupervisor(imm);
```

SWP, SWPA, SWPAL, SWPL

Swap word or doubleword in memory

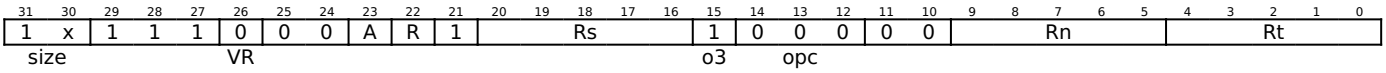
This instruction atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `SWPA` and `SWPAL` load from memory with acquire semantics.
- `SWPL` and `SWPAL` store to memory with release semantics.
- `SWP` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.

Integer

(FEAT_LSE)



Encoding for the 32-bit SWP variant

Applies when `(size == 10 && A == 0 && R == 0)`

```
SWP <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPA variant

Applies when `(size == 10 && A == 1 && R == 0)`

```
SWPA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPAL variant

Applies when `(size == 10 && A == 1 && R == 1)`

```
SWPAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPL variant

Applies when `(size == 10 && A == 0 && R == 1)`

```
SWPL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit SWP variant

Applies when `(size == 11 && A == 0 && R == 0)`

```
SWP <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPA variant

Applies when `(size == 11 && A == 1 && R == 0)`

```
SWPA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPAL variant

Applies when `(size == 11 && A == 1 && R == 1)`

```
SWPAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPL variant

Applies when `(size == 11 && A == 0 && R == 1)`

```
SWPL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;

let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 8 << UInt(size);
let regsize : integer{} = if datasize == 64 then 64 else 32;
let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register to be stored, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register to be stored, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Operation

```
var address : bits(64);
var data : bits(datasize);
var store_value : bits(datasize);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_SWP, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

store_value = X{datasize}(s);

// Irrelevant when not executing CAS
let comparevalue : bits(datasize) = ARBITRARY : bits(datasize);
data = MemAtomic{datasize}(address, comparevalue, store_value, accdesc);

X{regsize}(t) = ZeroExtend{regsize}(data);
```

SWPB, SWPAB, SWPALB, SWPLB

Swap byte in memory

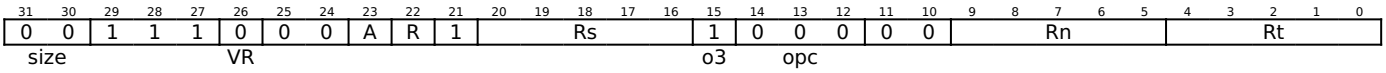
This instruction atomically loads an 8-bit byte from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `SWPAB` and `SWPALB` load from memory with acquire semantics.
- `SWPLB` and `SWPALB` store to memory with release semantics.
- `SWPB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.
For information about addressing modes, see *Load/Store addressing modes*.

Integer

(FEAT_LSE)



Encoding for the SWPB variant

Applies when `(A == 0 && R == 0)`

```
SWPB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPAB variant

Applies when `(A == 1 && R == 0)`

```
SWPAB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPALB variant

Applies when `(A == 1 && R == 1)`

```
SWPALB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPLB variant

Applies when `(A == 0 && R == 1)`

```
SWPLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF); end;

let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register to be stored, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
var data : bits(8);
var store_value : bits(8);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_SWP, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

store_value = X{8}(s);

// Irrelevant when not executing CAS
let comparevalue : bits(8) = ARBITRARY : bits(8);
data = MemAtomic{8}(address, comparevalue, store_value, accdesc);

X{32}(t) = ZeroExtend{32}(data);
```

SWPP, SWPPA, SWPPAL, SWPPL

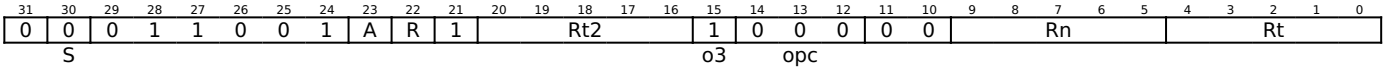
Swap quadword in memory

This instruction atomically loads a 128-bit quadword from a memory location, and stores the value held in a pair of registers back to the same memory location. The value initially loaded from memory is returned in the same pair of registers.

- SWPPA and SWPPAL load from memory with acquire semantics.
- SWPPL and SWPPAL store to memory with release semantics.
- SWPP has neither acquire nor release semantics.

Integer

(FEAT_LSE128)



Encoding for the SWPP variant

Applies when `(A == 0 && R == 0)`

```
SWPP <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the SWPPA variant

Applies when `(A == 1 && R == 0)`

```
SWPPA <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the SWPPAL variant

Applies when `(A == 1 && R == 1)`

```
SWPPAL <Xt1>, <Xt2>, [<Xn|SP>]
```

Encoding for the SWPPL variant

Applies when `(A == 0 && R == 1)`

```
SWPPL <Xt1>, <Xt2>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE128) then EndOfDecode(Decode_UNDEF); end;
if Rt  == '11111' then EndOfDecode(Decode_UNDEF); end;
if Rt2 == '11111' then EndOfDecode(Decode_UNDEF); end;

let t : integer{} = UInt(Rt);
let t2 : integer{} = UInt(Rt2);
let n : integer{} = UInt(Rn);
let acquire : boolean = A == '1';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;

var rt_unknown : boolean = FALSE;

if t == t2 then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_LSE128OVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN =>     rt_unknown = TRUE;     // result is UNKNOWN
        when Constraint_UNDEF =>       EndOfDecode(Decode_UNDEF);
        when Constraint_NOP =>         EndOfDecode(Decode_NOP);
    end;
end;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *128-bit Atomic Memory Operations*.

Assembler Symbols

<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
var address : bits(64);
let value1 : bits(64) = X{}(t);
let value2 : bits(64) = X{}(t2);
var data : bits(128);
var store_value : bits(128);

SWPT, SWPTA, SWPTAL, SWPTL

Swap unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `SWPTA` and `SWPTAL` load from memory with acquire semantics.
- `SWPTL` and `SWPTAL` store to memory with release semantics.
- `SWPT` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

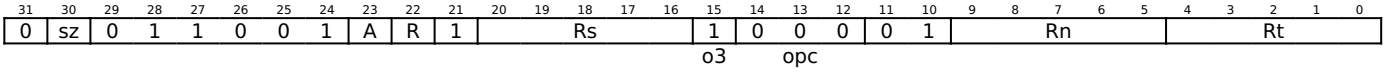
Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of *HCR_EL2()*.{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Integer

(FEAT_LSUI)



Encoding for the 32-bit SWPT variant

Applies when `(sz == 0 && A == 0 && R == 0)`

```
SWPT <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPTA variant

Applies when `(sz == 0 && A == 1 && R == 0)`

```
SWPTA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPTAL variant

Applies when `(sz == 0 && A == 1 && R == 1)`

```
SWPTAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPTL variant

Applies when `(sz == 0 && A == 0 && R == 1)`

```
SWPTL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPT variant

Applies when `(sz == 1 && A == 0 && R == 0)`

```
SWPT <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPTA variant

Applies when `(sz == 1 && A == 1 && R == 0)`

```
SWPTA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPTAL variant

Applies when `(sz == 1 && A == 1 && R == 1)`

```
SWPTAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPTL variant

Applies when `(sz == 1 && A == 0 && R == 1)`

```
SWPTL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSUI) then EndOfDecode(Decode_UNDEF); end;

let s : integer{} = UInt(Rs);
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);

let datasize : integer{} = 32 << UInt(sz);
let regsize : integer{} = if datasize == 64 then 64 else 32;
let acquire : boolean = A == '1' && Rt != '11111';
let release : boolean = R == '1';
let tagchecked : boolean = n != 31;
```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register to be stored, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register to be stored, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Operation

```
var address : bits(64);
var data : bits(datasize);
var store_value : bits(datasize);

let privileged : boolean = AArch64_IsUnprivAccessPriv();
let accdesc : AccessDescriptor = CreateAccDescAtomicOp(MemAtomicOp_SWP, acquire, release,
                                                       tagchecked, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

store_value = X{datasize}(s);

// Irrelevant when not executing CAS
let comparevalue : bits(datasize) = ARBITRARY : bits(datasize);
data = MemAtomic{datasize}(address, comparevalue, store_value, accdesc);

X{regsize}(t) = ZeroExtend{regsize}(data);
```

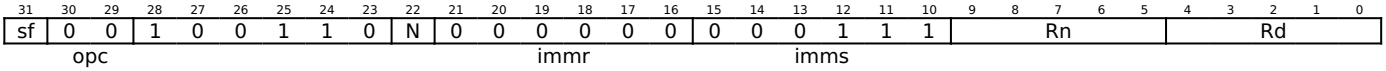
SXTB

Signed extend byte

This instruction extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SXTB <Wd>, <Wn>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #0, #7
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SXTB <Xd>, <Wn>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #0, #7
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

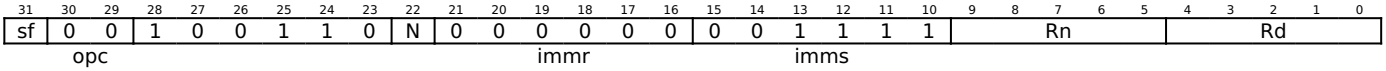
SXTH

Sign extend halfword

This instruction extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
SXTH <Wd>, <Wn>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #0, #15
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
SXTH <Xd>, <Wn>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #0, #15
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

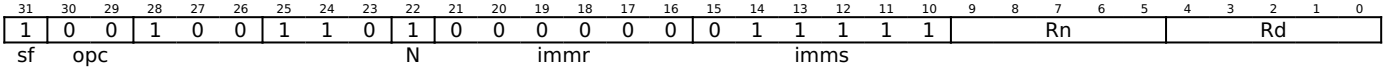
SXTW

Sign extend word

This instruction sign-extends a word to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
SXTW <Xd>, <Wn>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #0, #31
```

and is always the preferred disassembly.

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

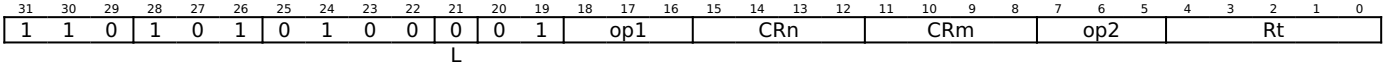
SYS

System instruction

For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions* for the encodings of System instructions.

This instruction is used by the aliases APAS, AT, BRB, CFP, COSP, CPP, DC, DVP, GCSPOPCX, GCSPOPX, GCSPUSHM, GCSPUSHX, GCSSS1, GIC, GSB, IC, TLBI, and TRCIT.



Encoding

```
SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

Decode for this encoding

```
let t : integer       = UInt(Rt);
let sys_op0 : bits(2) = '01';
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt>	Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Alias Conditions

Alias	Is preferred when
APAS	`op1 == '110' && CRn == '0111' && CRm == '0000' && op2 == '000'`
AT	`CRn == '0111' && CRm IN {'100x'} && SysOp(op1, '0111', CRm, op2) == Sys_AT`
BRB	`op1 == '001' && CRn == '0111' && CRm == '0010' && SysOp('001', '0111', '0010', op2) == Sys_BRB`
CFP	`op1 == '011' && CRn == '0111' && CRm == '0011' && op2 == '100'`
COSP	`op1 == '011' && CRn == '0111' && CRm == '0011' && op2 == '110'`
CPP	`op1 == '011' && CRn == '0111' && CRm == '0011' && op2 == '111'`
DC	`CRn == '0111' && SysOp(op1, '0111', CRm, op2) == Sys_DC`
DVP	`op1 == '011' && CRn == '0111' && CRm == '0011' && op2 == '101'`
GCSPOPCX	`op1 == '000' && CRn == '0111' && CRm == '0111' && op2 == '101'`
GCSPOPX	`op1 == '000' && CRn == '0111' && CRm == '0111' && op2 == '110'`
GCSPUSHM	`op1 == '011' && CRn == '0111' && CRm == '0111' && op2 == '000'`
GCSPUSHX	`op1 == '000' && CRn == '0111' && CRm == '0111' && op2 == '100'`
GCSSS1	`op1 == '011' && CRn == '0111' && CRm == '0111' && op2 == '010'`
GIC	`CRn == '1100' && CRm IN {'0001', '0010'} && SysOp(op1, '1100', CRm, op2) == Sys_GIC`
GSB	`op1 == '000' && CRn == '1100' && CRm == '0000' && SysOp('000', '1100', '0000', op2) == Sys_GSB`
IC	`CRn == '0111' && SysOp(op1, '0111', CRm, op2) == Sys_IC`
TLBI	`CRn IN {'100x'} && SysOp(op1, CRn, CRm, op2) == Sys_TLBI`
TRCIT	`op1 == '011' && CRn == '0111' && CRm == '0010' && op2 == '111'`

Operation

```
AArch64_SysInstr(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

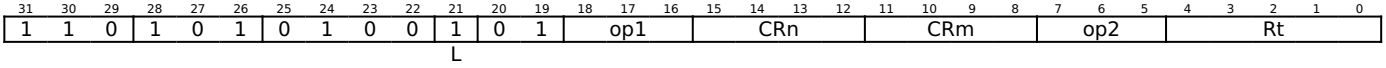
SYSL

System instruction with result

For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions* for the encodings of System instructions.

This instruction is used by the aliases GCSPOPM, GCSSS2, and GICR.



Encoding

```
SYSL <Xt>, #<op1>, <Cn>, <Cm>, #<op2>
```

Decode for this encoding

```
let t : integer       = UInt(Rt);
let sys_op0 : bits(2) = '01';
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Alias Conditions

Alias	Is preferred when
GCSPOPM	`op1 == '011' && CRn == '0111' && CRm == '0111' && op2 == '001'`
GCSSS2	`op1 == '011' && CRn == '0111' && CRm == '0111' && op2 == '011'`
GICR	`op1 == '000' && CRn == '1100' && CRm == '0011' && SysLOp('000', '1100', '0011', op2) == Sysl_GICR`

Operation

```
AArch64_SysInstrWithResult(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

SYSP

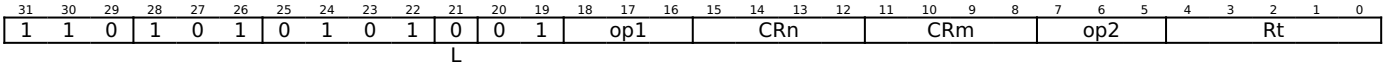
128-bit system instruction

For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions* for the encodings of System instructions.

This instruction is used by the alias TLBIP.

System

(FEAT_SYSINSTR128)



Encoding

```
SYSP #<op1>, <Cn>, <Cm>, #<op2>{, <Xt1>, <Xt2>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SYSINSTR128) then EndOfDecode(Decode_UNDEF); end;
if Rt[0] == '1' && Rt != '11111' then EndOfDecode(Decode_UNDEF); end;

let t : integer       = UInt(Rt);
let t2 : integer      = if t == 31 then 31 else t + 1;
let sys_op0 : bits(2) = '01';
let sys_op1 : bits(3) = op1;
let sys_op2 : bits(3) = op2;
let sys_crn : bits(4) = CRn;
let sys_crm : bits(4) = CRm;
```

Assembler Symbols

<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt1>	Is the 64-bit name of the first optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second optional general-purpose source register, defaulting to '11111', encoded as "Rt" +1. Defaults to '11111' if "Rt" = '11111'.

Alias Conditions

Alias	Is preferred when
TLBIP	`CRn IN {'100x'} && SysOp128(op1, CRn, CRm, op2) == Sys_TLBIP`

Operation

```
AArch64_SysInstr128(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, t2);
```

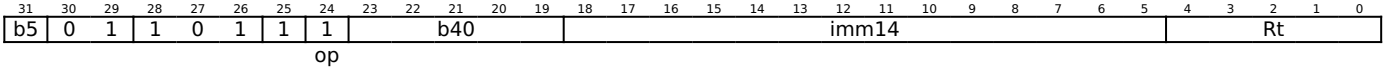
TBNZ

Test bit and branch if nonzero

This instruction compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



Encoding

```
TBNZ <R><t>, #<imm>, <label>
```

Decode for this encoding

```
let t : integer = UInt(Rt);

let datasize : integer{} = 32 << UInt(b5);
let bit_pos : integer = UInt(b5::b40);
let offset : bits(64) = SignExtend{}(imm14::'00');
```

Assembler Symbols

<R> Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is permitted only when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

```
let operand : bits(datasize) = X{datasize}(t);
let branch_conditional : boolean = TRUE;
if operand[bit_pos] != '0' then
    BranchTo{64}(PC64() + offset, BranchType_DIR, branch_conditional);
else
    BranchNotTaken(BranchType_DIR, branch_conditional);
end;
```

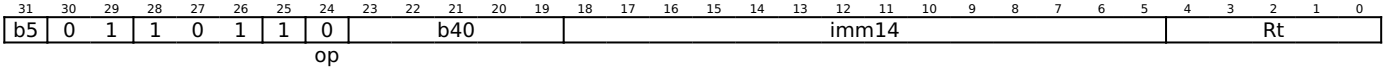
TBZ

Test bit and branch if zero

This instruction compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



Encoding

```
TBZ <R><t>, #<imm>, <label>
```

Decode for this encoding

```
let t : integer = UInt(Rt);

let datasize : integer{} = 32 << UInt(b5);
let bit_pos : integer = UInt(b5::b40);
let offset : bits(64) = SignExtend{}(imm14::'00');
```

Assembler Symbols

<R> Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is permitted only when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

```
let operand : bits(datasize) = X{datasize}(t);
let branch_conditional : boolean = TRUE;
if operand[bit_pos] == '0' then
    BranchTo{64}(PC64() + offset, BranchType_DIR, branch_conditional);
else
    BranchNotTaken(BranchType_DIR, branch_conditional);
end;
```

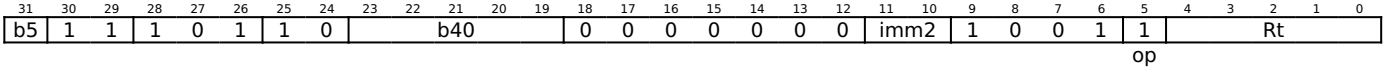
TFLTNZ

Test bit and fault if nonzero

This instruction compares the value of a bit in a general-purpose register with zero, and conditionally generates a Conditional fault exception if the comparison is not equal. This instruction does not affect condition flags.

Fault

(FEAT_CFLT)



Encoding

```
TFLTNZ #<reason>, <R><t>, #<imm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CFLT) then EndOfDecode(Decode_UNDEF); end;

let datasize : integer{} = 32 << UInt(b5);
let t : integer = UInt(Rt);
let bit_pos : integer = UInt(b5::b40);
let reason : bits(16) = ZeroExtend{}(imm2);
```

Assembler Symbols

<reason> Is a 2-bit unsigned immediate, in the range 0 to 3, encoded in the "imm2" field.

<R> Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is permitted only when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

Operation

```
CheckCFLTEnabled();

let operand : bits(datasize) = X{}(t);

if operand[bit_pos] != '0' then
    let isflt : boolean = FALSE;
    AArch64_ConditionalFault(isflt, reason);
end;
```

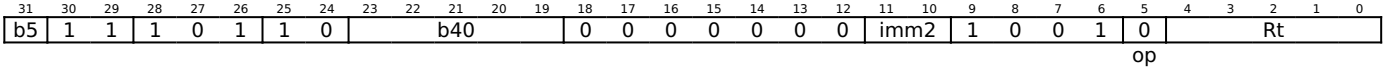
TFLTZ

Test bit and fault if zero

This instruction compares the value of a bit in a general-purpose register with zero, and conditionally generates a Conditional fault exception if the comparison is equal. This instruction does not affect condition flags.

Fault

(FEAT_CFLT)



Encoding

```
TFLTZ #<reason>, <R><t>, #<imm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CFLT) then EndOfDecode(Decode_UNDEF); end;

let datasize : integer{} = 32 << UInt(b5);
let t : integer = UInt(Rt);
let bit_pos : integer = UInt(b5::b40);
let reason : bits(16) = ZeroExtend{}(imm2);
```

Assembler Symbols

<reason> Is a 2-bit unsigned immediate, in the range 0 to 3, encoded in the "imm2" field.

<R> Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is permitted only when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

Operation

```
CheckCFLTEnabled();

let operand : bits(datasize) = X{}(t);

if operand[bit_pos] == '0' then
    let isflt : boolean = FALSE;
    AArch64_ConditionalFault(isflt, reason);
end;
```

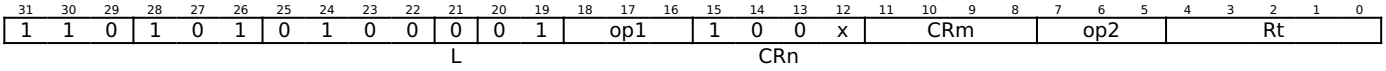
TLBI

TLB invalidate operation

For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions*.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
TLBI <tlbi_op>{, <Xt>}
```

is equivalent to

```
SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1, CRn, CRm, op2) == Sys_TLBI`.

<tlbi_op> Is a TLBI operation name, as listed for the TLBI system instruction group, encoded in “(op1 :: CRn :: CRm :: op2)”:

op1	CRn	CRm	op2	<tlbi_op>	Architectural Feature	Description
000	1000	0001	000	VMALLE1OS	FEAT_TLBIOS	For more information, see TLBI VMALLE1OS, TLBI VMALLE1OSNXS.
000	1000	0001	001	VAE1OS	FEAT_TLBIOS	For more information, see TLBI VAE1OS, TLBI VAE1OSNXS.
000	1000	0001	010	ASIDE1OS	FEAT_TLBIOS	For more information, see TLBI ASIDE1OS, TLBI ASIDE1OSNXS.

110	1001	0111	101	VALE3NXS	FEAT_XS	For more information, see TLBI VALE3, TLBI VALE3NXS.

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

2026-09_rel 2026-09-21 14:22:38

TLBIP

TLB invalidate pair operation

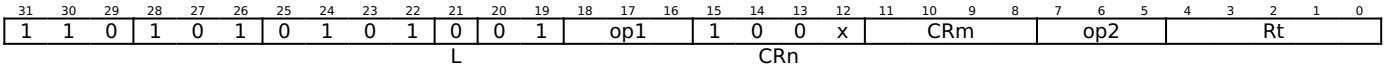
For more information, see *op0 == 0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, BRBE, Trace Extension, Guarded Control Stack, and FEAT_RME_GPC3 instructions*.

This is an alias of SYSP. This means:

- The encodings in this description are named to match the encodings of SYSP.
- The description of SYSP gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SYSINSTR128)



Encoding

```
TLBIP <tlbip_op>{, <Xt1>, <Xt2>}
```

is equivalent to

```
SYSP #<op1>, <Cn>, <Cm>, #<op2>{, <Xt1>, <Xt2>}
```

and is the preferred disassembly when `SysOp128(op1, CRn, CRm, op2) == Sys_TLBIP`.

<tlbip_op> Is a TLBIP operation name, as listed for the TLBIP system pair instruction group, encoded in “(op1 :: CRn :: CRm :: op2)”:

<Xt1> Is the 64-bit name of the first optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second optional general-purpose source register, defaulting to '11111', encoded as "Rt" +1. Defaults to '11111' if "Rt" = '11111'.

Operation

The description of SYSP gives the operational pseudocode for this instruction.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

TRCIT

Trace instrumentation

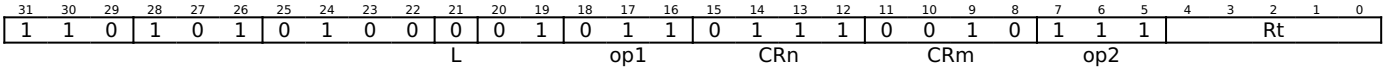
This instruction generates an instrumentation trace packet that contains the value of the provided register.
For more information, see TRCIT, Trace Instrumentation.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_ITE)



Encoding

```
TRCIT <Xt>
```

is equivalent to

```
SYS #3, C7, C2, #7, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

TSB

Trace synchronization barrier

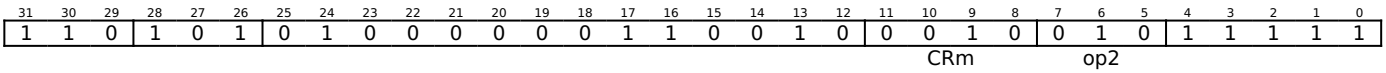
This instruction is a barrier that synchronizes the trace operations of instructions, see *Trace Synchronization Barrier (TSB)*. For information about the synchronization behavior when a `DSB` instruction follows a `TSB` instruction in program order, see:

- *Trace synchronization and memory barriers*.
- *Synchronization in self-hosted trace*.

If *FEAT_TRF* is not implemented, this instruction executes as a `NOP`.

System

(FEAT_TRF)



Encoding

```
TSB CSYNC
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_TRF) then EndOfDecode(Decode_NOP); end;
```

Operation

```
CheckTSBTrap();

TraceSynchronizationBarrier();
```

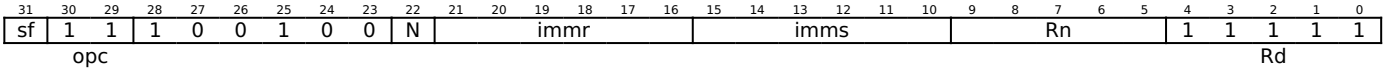
TST (immediate)

Test bits (immediate)

This instruction performs a bitwise AND between a register value and an immediate value, and discards the results. It updates the condition flags based on the result.

This is an alias of ANDS (immediate). This means:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
TST <Wn>, #<imm>
```

is equivalent to

```
ANDS WZR, <Wn>, #<imm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
TST <Xn>, #<imm>
```

is equivalent to

```
ANDS XZR, <Xn>, #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	Is the bitmask immediate. For encoding information, see *Logical (immediate)*.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ANDS (immediate) gives the operational information for this instruction.

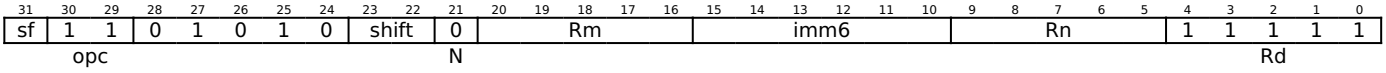
TST (shifted register)

Test (shifted register)

This instruction performs a bitwise AND between a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ANDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
TST <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ANDS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
TST <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ANDS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ANDS (shifted register) gives the operational information for this instruction.

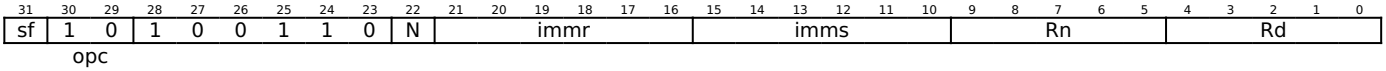
UBFIZ

Unsigned bitfield insert in zeros

This instruction copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits above and below the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
UBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
UBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

UBFM

Unsigned bitfield move

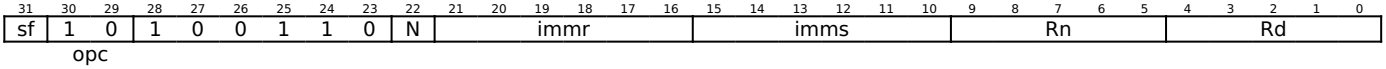
This instruction is usually accessed using one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
UBFM <Wd>, <Wn>, #<immr>, #<imms>
```

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
UBFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
if sf == '1' && N != '1' then EndOfDecode(Decode_UNDEF); end;
if sf == '0' && (N != '0' || immr[5] != '0' || imms[5] != '0') then
    EndOfDecode(Decode_UNDEF);
end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let r : integer = UInt(immr);

var wmask : bits(datasize);
var tmask : bits(datasize);
(wmask, tmask) = DecodeBitMasks{datasize}(N, imms, immr, FALSE);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<immr>	For the "32-bit" variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the "64-bit" variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
<imms>	For the "32-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the "64-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Of variant	Is preferred when
LSL (immediate)	32-bit	`imms != '011111' && UInt(imms) + 1 == UInt(immr)`
LSL (immediate)	64-bit	`imms != '111111' && UInt(imms) + 1 == UInt(immr)`
LSR (immediate)	32-bit	`imms == '011111'`
LSR (immediate)	64-bit	`imms == '111111'`
UBFIZ		`UInt(imms) < UInt(immr)`
UBFX		`BFXPreferred(sf, opc[1], imms, immr)`
UXTB		`immr == '000000' && imms == '000111'`
UXTH		`immr == '000000' && imms == '001111'`

Operation

```
let src : bits(datasize) = X{}(n);

// Perform bitfield move on low bits
let bot : bits(datasize) = ROR(src, r) AND wmask;

// Combine extension bits and result bits
X{datasize}(d) = bot AND tmask;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

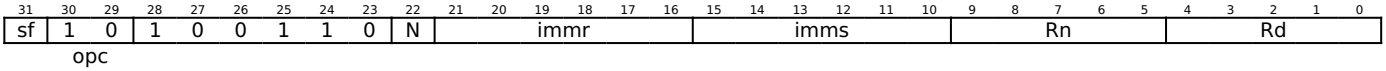
UBFX

Unsigned bitfield extract

This instruction copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant

Applies when `(sf == 0 && N == 0)`

```
UBFX <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc[1], imms, immr)`.

Encoding for the 64-bit variant

Applies when `(sf == 1 && N == 1)`

```
UBFX <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc[1], imms, immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

UDF

Permanently undefined

This instruction generates an Undefined Instruction exception (*ESR_ELx*.EC = 0b000000). The encodings for `UDF` used in this section are defined as permanently UNDEFINED.

Encoding

```
UDF #<imm>
```

Decode for this encoding

```
// The imm16 field is ignored by hardware.
EndOfDecode(Decode_UNDEF);
```

Assembler Symbols

<imm>	is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field. The PE ignores the value of this constant.

Operation

```
// No operation.
```

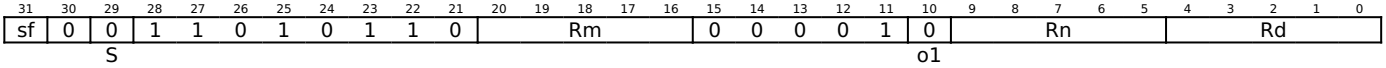
Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

UDIV (quotient)

Unsigned divide

This instruction divides the first unsigned source register value by the second unsigned source register value, and writes the result to the destination register. Dividing by zero writes the value zero to the destination register. The condition flags are not affected.



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
UDIV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
UDIV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let dividend : integer = UInt(operand1);
let divisor : integer = UInt(operand2);

var result : integer;
if divisor == 0 then
    result = 0;
else
    result = dividend DIVRM divisor;
end;

X{datasize}(d) = result[datasize-1:0];
```

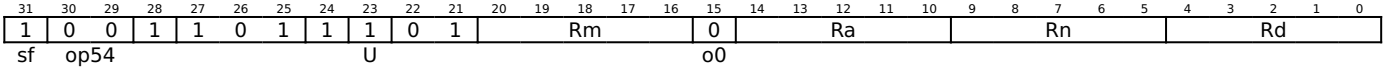
UMADDL

Unsigned multiply-add long

This instruction multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.
This instruction is used by the alias UMULL (32-bit).



Encoding

```
UMADDL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
UMULL (32-bit)	`Ra == '11111'`

Operation

```
let operand1 : bits(32) = X{32}(n);
let operand2 : bits(32) = X{32}(m);
let operand3 : bits(64) = X{64}(a);

let result : integer = UInt(operand3) + UInt(operand1) * UInt(operand2);

X{64}(d) = result[63:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

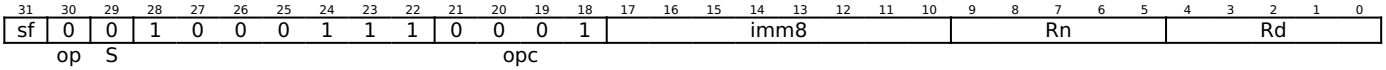
UMAX (immediate)

Unsigned maximum (immediate)

This instruction determines the unsigned maximum of the source register value and immediate, and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
UMAX <Wd>, <Wn>, #<uimm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
UMAX <Xd>, <Xn>, #<uimm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let imm : integer = UInt(imm8);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<uimm>	Is an unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = Max(UInt(operand1), imm);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

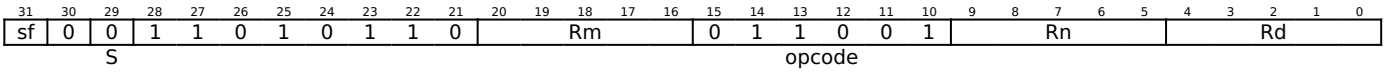
UMAX (register)

Unsigned maximum (register)

This instruction determines the unsigned maximum of the two source register values and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
UMAX <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
UMAX <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let result : integer = Max(UInt(operand1), UInt(operand2));

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

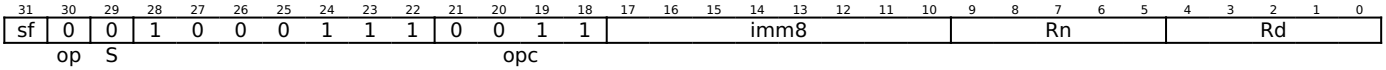
UMIN (immediate)

Unsigned minimum (immediate)

This instruction determines the unsigned minimum of the source register value and immediate, and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
UMIN <Wd>, <Wn>, #<uimm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
UMIN <Xd>, <Xn>, #<uimm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 32 << UInt(sf);
let imm : integer = UInt(imm8);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<uimm>	Is an unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let result : integer = Min(UInt(operand1), imm);

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

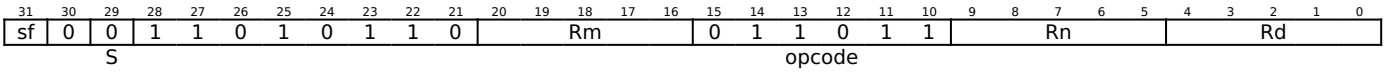
UMIN (register)

Unsigned minimum (register)

This instruction determines the unsigned minimum of the two source register values and writes the result to the destination register.

Integer

(FEAT_CSSC)



Encoding for the 32-bit variant

Applies when `(sf == 0)`

```
UMIN <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant

Applies when `(sf == 1)`

```
UMIN <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CSSC) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
let operand1 : bits(datasize) = X{datasize}(n);
let operand2 : bits(datasize) = X{datasize}(m);
let result : integer = Min(UInt(operand1), UInt(operand2));

X{datasize}(d) = result[datasize-1:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

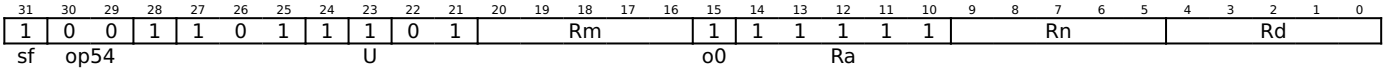
UMNEGL

Unsigned multiply-negate long

This instruction multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This is an alias of UMSUBL. This means:

- The encodings in this description are named to match the encodings of UMSUBL.
- The description of UMSUBL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

`UMNEGL <Xd>, <Wn>, <Wm>`

is equivalent to

`UMSUBL <Xd>, <Wn>, <Wm>, XZR`

and is always the preferred disassembly.

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of UMSUBL gives the operational pseudocode for this instruction.

Operational Information

The description of UMSUBL gives the operational information for this instruction.

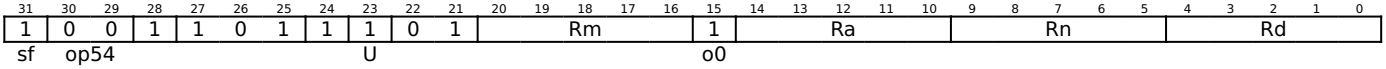
UMSUBL

Unsigned multiply-subtract long

This instruction multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMNEGL.



Encoding

```
UMSUBL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
UMNEGL	`Ra == '11111'`

Operation

```
let operand1 : bits(32) = X{32}(n);
let operand2 : bits(32) = X{32}(m);
let operand3 : bits(64) = X{64}(a);

let result : integer = UInt(operand3) - UInt(operand1) * UInt(operand2);

X{64}(d) = result[63:0];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

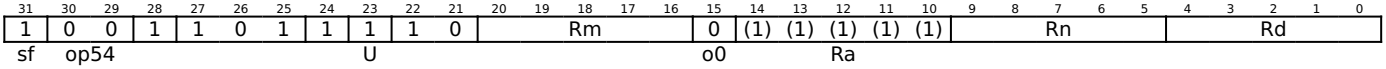
UMULH

Unsigned multiply high

This instruction multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.



Encoding

```
UMULH <Xd>, <Xn>, <Xm>
```

Decode for this encoding

```
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
let operand1 : bits(64) = X{64}(n);
let operand2 : bits(64) = X{64}(m);

let result : integer = UInt(operand1) * UInt(operand2);

X{64}(d) = result[127:64];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

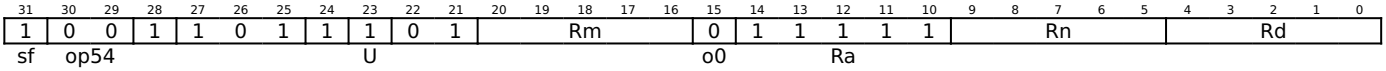
UMULL (32-bit)

Unsigned multiply long

This instruction multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This is an alias of UMADDL. This means:

- The encodings in this description are named to match the encodings of UMADDL.
- The description of UMADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

`UMULL` <Xd>, <Wn>, <Wm>

is equivalent to

UMADDL <Xd>, <Wn>, <Wm>, `XZR`

and is always the preferred disassembly.

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of UMADDL gives the operational pseudocode for this instruction.

Operational Information

The description of UMADDL gives the operational information for this instruction.

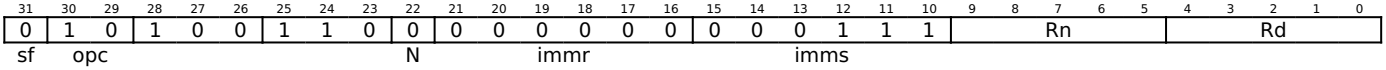
UXTB

Unsigned extend byte

This instruction extracts an 8-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
UXTB <Wd>, <Wn>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #0, #7
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

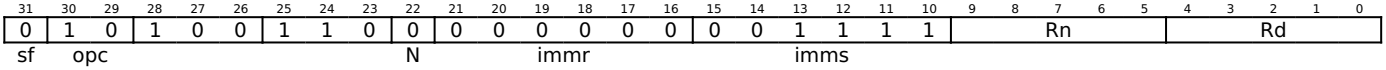
UXTH

Unsigned extend halfword

This instruction extracts a 16-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
UXTH <Wd>, <Wn>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #0, #15
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

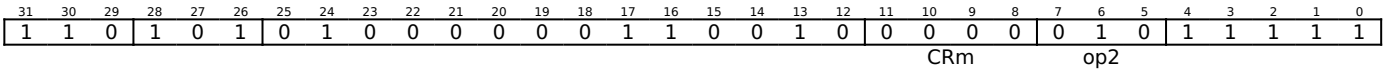
WFE

Wait for event

This instruction is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the `SEV` instruction on any PE in the multiprocessor system. For more information, see *Wait For Event mechanism and Send event*.

As described in *Wait For Event mechanism and Send event*, the execution of a `WFE` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.



Encoding

```
WFE
```

Decode for this encoding

```
// Empty.
```

Operation

```
Hint_WFE();
```

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

WFET

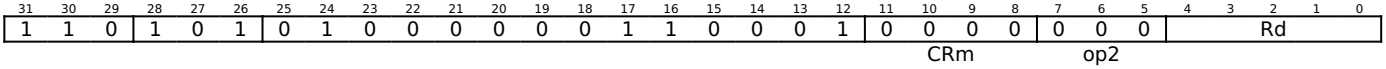
Wait for event with timeout

This instruction provides a hint that the PE can enter a low-power state and remain there until either a local timeout event or a wakeup event occurs. Wakeup events include the event signaled as a result of executing the `SEV` instruction on any PE in the multiprocessor system. For more information, see *Wait For Event mechanism and Send event*.

As described in *Wait For Event mechanism and Send event*, the execution of a `WFET` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

System

(FEAT_WFxT)



Encoding

```
WFET <Xt>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_WFxT) then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rd" field.

Operation

```
let localtimeout : integer = UInt(X{64}(d));

if Halted() && ConstrainUnpredictableBool(Unpredictable_WFxTDEBUG) then
    ExecuteAsNOP();
end;

Hint_WFET(localtimeout);
```

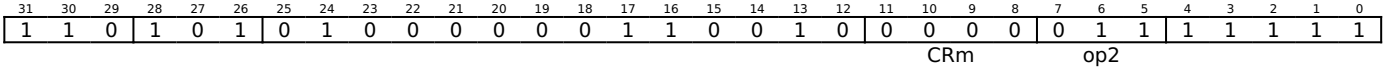
WFI

Wait for interrupt

This instruction is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. For more information, see *Wait For Interrupt*.

As described in *Wait For Interrupt*, the execution of a `WFI` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.



Encoding

```
WFI
```

Decode for this encoding

```
// Empty.
```

Operation

```
Hint_WFI();
```

WFIT

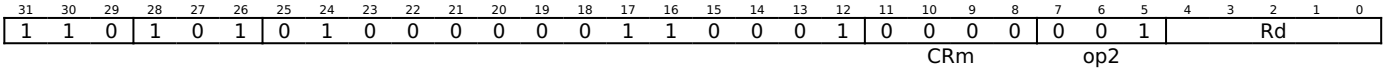
Wait for interrupt with timeout

This instruction provides a hint that the PE can enter a low-power state and remain there until either a local timeout event or a wakeup event occurs. For more information, see *Wait For Interrupt*.

As described in *Wait For Interrupt*, the execution of a `WFIT` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

System

(FEAT_WFxT)



Encoding

```
WFIT <Xt>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_WFxT) then EndOfDecode(Decode_UNDEF); end;

let d : integer = UInt(Rd);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rd" field.

Operation

```
let localtimeout : integer = UInt(X{64}(d));

if Halted() && ConstrainUnpredictableBool(Unpredictable_WFxTDEBUG) then
    ExecuteAsNOP();
end;

Hint_WFIT(localtimeout);

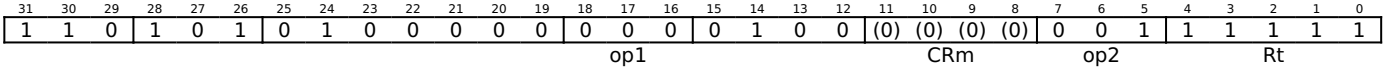
XAFLAG

Convert floating-point condition flags from external format to Arm format

This instruction converts the state of the PSTATE.{N,Z,C,V} flags from an alternative representation required by some software to a form representing the result of an Arm floating-point scalar compare instruction.

System

(FEAT_FlagM2)



Encoding

XAFLAG

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_FlagM2) then EndOfDecode(Decode_UNDEF); end;
```

Operation

```
let n : bit = NOT PSTATE.C AND NOT PSTATE.Z;
let z : bit = PSTATE.Z AND PSTATE.C;
let c : bit = PSTATE.C OR PSTATE.Z;
let v : bit = NOT PSTATE.C AND PSTATE.Z;

PSTATE.N = n;
PSTATE.Z = z;
PSTATE.C = c;
PSTATE.V = v;
```

XPACD, XPACI, XPACLRI

Strip Pointer Authentication Code

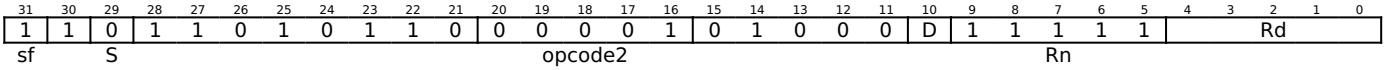
This instruction removes the Pointer Authentication Code from an address. The address is in the specified general-purpose register for `XPACI` and `XPACD`, and is in LR for `XPACLRI`.

The `XPACD` instruction is used for data addresses, and `XPACI` and `XPACLRI` are used for instruction addresses.

It has encodings from 2 classes: Integer and System

Integer

(FEAT_PAuth)



Encoding for the XPACD variant

Applies when `(D == 1)`

```
XPACD <Xd>
```

Encoding for the XPACI variant

Applies when `(D == 0)`

```
XPACI <Xd>
```

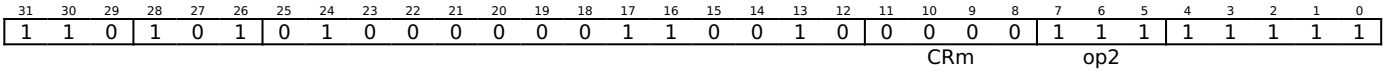
Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let data : boolean = D == '1';
```

System

(FEAT_PAuth)



Encoding

```
XPACLRI
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_NOP); end;

let d : integer{} = 30;
let data : boolean = FALSE;
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

```
X{64}(d) = Strip(X{64}(d), data);
```

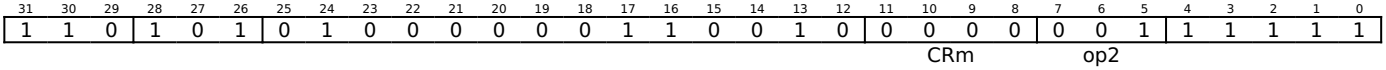
YIELD

Yield

This instruction is a hint instruction. Software with a multithreading capability can use a `YIELD` instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see *The YIELD instruction*.



Encoding

```
YIELD
```

Decode for this encoding

```
// Empty.
```

Operation

```
Hint_Yield();
```

A64 -- SIMD and Floating-point Instructions (alphabetic order)

ABS: Absolute value (vector).

ADD (vector): Add (vector).

ADDHN, ADDHN2: Add returning high narrow.

ADDP (scalar): Add pair of elements (scalar).

ADDP (vector): Add pairwise (vector).

ADDV: Add across vector.

AESD: AES single round decryption.

AESE: AES single round encryption.

AESIMC: AES inverse mix columns.

AESMC: AES mix columns.

AND (vector): Bitwise AND (vector).

BCAX: Bit clear and exclusive-OR.

BF1CVTL, BF1CVTL2, BF2CVTL, BF2CVTL2: 8-bit floating-point convert to BFloat16 (vector).

BFCVT: Single-precision convert to BFloat16 (scalar).

BFCVTN, BFCVTN2: Single-precision convert to BFloat16 (vector).

BFDOT (by element): BFloat16 dot product to single-precision (vector, by element).

BFDOT (vector): BFloat16 dot product to single-precision (vector).

BFMLALB, BFMLALT (by element): BFloat16 multiply-add to single-precision (by element).

BFMLALB, BFMLALT (vector): BFloat16 multiply-add to single-precision (vector).

BFMMLA (widening): BFloat16 matrix multiply-accumulate to single-precision.

BIC (vector, immediate): Bitwise bit clear (vector, immediate).

BIC (vector, register): Bitwise bit clear (vector, register).

BIF: Bitwise insert if false.

BIT: Bitwise insert if true.

BSL: Bitwise select.

CLS (vector): Count leading sign bits (vector).

CLZ (vector): Count leading zero bits (vector).

CMEQ (register): Compare bitwise equal (vector).

CMEQ (zero): Compare bitwise equal to zero (vector).

CMGE (register): Compare signed greater than or equal (vector).

CMGE (zero): Compare signed greater than or equal to zero (vector).

CMGT (register): Compare signed greater than (vector).

CMGT (zero): Compare signed greater than zero (vector).

CMHI (register): Compare unsigned higher (vector).

CMHS (register): Compare unsigned higher or same (vector).

CMLE (zero): Compare signed less than or equal to zero (vector).

CMLT (zero): Compare signed less than zero (vector).

CMTST: Compare bitwise test bits nonzero (vector).

CNT: Population count per byte.

DUP (element): Duplicate vector element to vector or scalar.

DUP (general): Duplicate general-purpose register to vector.

EOR (vector): Bitwise exclusive-OR (vector).

EOR3: Three-way exclusive-OR.

EXT: Extract vector from pair of vectors.

F1CVTL, F1CVTL2, F2CVTL, F2CVTL2: 8-bit floating-point convert to half-precision (vector).

FABD: Floating-point absolute difference (vector).

FABS (scalar): Floating-point absolute value (scalar).

FABS (vector): Floating-point absolute value (vector).

FACGE: Floating-point absolute compare greater than or equal (vector).

FACGT: Floating-point absolute compare greater than (vector).

FADD (scalar): Floating-point add (scalar).

FADD (vector): Floating-point add (vector).

FADDP (scalar): Floating-point add pair of elements (scalar).

FADDP (vector): Floating-point add pairwise (vector).

FAMAX: Floating-point absolute maximum.

FAMIN: Floating-point absolute minimum.

FCADD: Floating-point complex add.

FCCMP: Floating-point conditional quiet compare (scalar).

FCCMPE: Floating-point conditional signaling compare (scalar).

FCMEQ (register): Floating-point compare equal (vector).

FCMEQ (zero): Floating-point compare equal to zero (vector).

FCMGE (register): Floating-point compare greater than or equal (vector).

FCMGE (zero): Floating-point compare greater than or equal to zero (vector).

FCMGT (register): Floating-point compare greater than (vector).

FCMGT (zero): Floating-point compare greater than zero (vector).

FCMLA: Floating-point complex multiply accumulate.

FCMLA (by element): Floating-point complex multiply accumulate (by element).

FCMLE (zero): Floating-point compare less than or equal to zero (vector).

FCMLT (zero): Floating-point compare less than zero (vector).

FCMP: Floating-point quiet compare (scalar).

FCMPE: Floating-point signaling compare (scalar).

FCSEL: Floating-point conditional select (scalar).

FCVT: Floating-point convert precision (scalar).

FCVTAS (scalar SIMD&FP): Floating-point convert to signed integer, rounding to nearest with ties to away (scalar SIMD&FP).

FCVTAS (scalar): Floating-point convert to signed integer, rounding to nearest with ties to away (scalar).

FCVTAS (vector): Floating-point convert to signed integer, rounding to nearest with ties to away (vector).

FCVTAU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding to nearest with ties to away (scalar SIMD&FP).

FCVTAU (scalar): Floating-point convert to unsigned integer, rounding to nearest with ties to away (scalar).

FCVTAU (vector): Floating-point convert to unsigned integer, rounding to nearest with ties to away (vector).

FCVTL, FCVTL2: Floating-point convert to higher precision long (vector).

FCVTMS (scalar SIMD&FP): Floating-point convert to signed integer, rounding toward minus infinity (scalar SIMD&FP).

FCVTMS (scalar): Floating-point convert to signed integer, rounding toward minus infinity (scalar).

FCVTMS (vector): Floating-point convert to signed integer, rounding toward minus infinity (vector).

FCVTMU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding toward minus infinity (scalar SIMD&FP).

FCVTMU (scalar): Floating-point convert to unsigned integer, rounding toward minus infinity (scalar).

FCVTMU (vector): Floating-point convert to unsigned integer, rounding toward minus infinity (vector).

FCVTN (half-precision to 8-bit floating-point): Half-precision convert to 8-bit floating-point (vector).

FCVTN, FCVTN2 (double to single-precision, single to half-precision): Floating-point convert to lower precision narrow (vector).

FCVTN, FCVTN2 (single-precision to 8-bit floating-point): Single-precision convert to 8-bit floating-point (vector).

FCVTNS (scalar SIMD&FP): Floating-point convert to signed integer, rounding to nearest with ties to even (scalar SIMD&FP).

FCVTNS (scalar): Floating-point convert to signed integer, rounding to nearest with ties to even (scalar).

FCVTNS (vector): Floating-point convert to signed integer, rounding to nearest with ties to even (vector).

FCVTNU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding to nearest with ties to even (scalar SIMD&FP).

FCVTNU (scalar): Floating-point convert to unsigned integer, rounding to nearest with ties to even (scalar).

FCVTNU (vector): Floating-point convert to unsigned integer, rounding to nearest with ties to even (vector).

FCVTPS (scalar SIMD&FP): Floating-point convert to signed integer, rounding toward plus infinity (scalar SIMD&FP).

FCVTPS (scalar): Floating-point convert to signed integer, rounding toward plus infinity (scalar).

FCVTPS (vector): Floating-point convert to signed integer, rounding toward plus infinity (vector).

FCVTPU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding toward plus infinity (scalar SIMD&FP).

FCVTPU (scalar): Floating-point convert to unsigned integer, rounding toward plus infinity (scalar).

FCVTPU (vector): Floating-point convert to unsigned integer, rounding toward plus infinity (vector).

FCVTXN, FCVTXN2: Floating-point convert to lower precision narrow, rounding to odd (vector).

FCVTZS (scalar SIMD&FP): Floating-point convert to signed integer, rounding toward zero (scalar SIMD&FP).

FCVTZS (scalar, fixed-point): Floating-point convert to signed fixed-point, rounding toward zero (scalar).

FCVTZS (scalar, integer): Floating-point convert to signed integer, rounding toward zero (scalar).

FCVTZS (vector, fixed-point): Floating-point convert to signed fixed-point, rounding toward zero (vector).

FCVTZS (vector, integer): Floating-point convert to signed integer, rounding toward zero (vector).

FCVTZU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding toward zero (scalar SIMD&FP).

FCVTZU (scalar, fixed-point): Floating-point convert to unsigned fixed-point, rounding toward zero (scalar).

FCVTZU (scalar, integer): Floating-point convert to unsigned integer, rounding toward zero (scalar).

FCVTZU (vector, fixed-point): Floating-point convert to unsigned fixed-point, rounding toward zero (vector).

FCVTZU (vector, integer): Floating-point convert to unsigned integer, rounding toward zero (vector).

FDIV (scalar): Floating-point divide (scalar).

FDIV (vector): Floating-point divide (vector).

FDOT (8-bit floating-point to half-precision, by element): 8-bit floating-point dot product to half-precision (vector, by element).

FDOT (8-bit floating-point to half-precision, vector): 8-bit floating-point dot product to half-precision (vector).

FDOT (8-bit floating-point to single-precision, by element): 8-bit floating-point dot product to single-precision (vector, by element).

FDOT (8-bit floating-point to single-precision, vector): 8-bit floating-point dot product to single-precision (vector).

FDOT (half-precision to single-precision, by element): Half-precision dot product to single-precision (vector, by element).

FDOT (half-precision to single-precision, vector): Half-precision dot product to single-precision (vector).

FJCVTZS: Floating-point JavaScript convert to signed fixed-point, rounding toward zero.

FMADD: Floating-point fused multiply-add (scalar).

FMAX (scalar): Floating-point maximum (scalar).

FMAX (vector): Floating-point maximum (vector).

FMAXNM (scalar): Floating-point maximum number (scalar).

FMAXNM (vector): Floating-point maximum number (vector).

FMAXNMP (scalar): Floating-point maximum number of pair of elements (scalar).

FMAXNMP (vector): Floating-point maximum number pairwise (vector).

FMAXNMV: Floating-point maximum number across vector.

FMAXP (scalar): Floating-point maximum of pair of elements (scalar).

FMAXP (vector): Floating-point maximum pairwise (vector).

FMAXV: Floating-point maximum across vector.

FMIN (scalar): Floating-point minimum (scalar).

FMIN (vector): Floating-point minimum (vector).

FMINNM (scalar): Floating-point minimum number (scalar).

FMINNM (vector): Floating-point minimum number (vector).

FMINNMP (scalar): Floating-point minimum number of pair of elements (scalar).

FMINNMP (vector): Floating-point minimum number pairwise (vector).

FMINNMV: Floating-point minimum number across vector.

FMINP (scalar): Floating-point minimum of pair of elements (scalar).

FMINP (vector): Floating-point minimum pairwise (vector).

FMINV: Floating-point minimum across vector.

FMLA (by element): Floating-point fused multiply-add to accumulator (by element).

FMLA (vector): Floating-point fused multiply-add to accumulator (vector).

FMLAL, FMLAL2 (by element): Floating-point fused multiply-add long to accumulator (by element).

FMLAL, FMLAL2 (vector): Floating-point fused multiply-add long to accumulator (vector).

FMLALB, FMLALT (by element): 8-bit floating-point multiply-add to half-precision (vector, by element).

FMLALB, FMLALT (vector): 8-bit floating-point multiply-add to half-precision (vector).

FMLALLBB, FMLALLBT, FMLALLTB, FMLALLTT (by element): 8-bit floating-point multiply-add to single-precision (vector, by element).

FMLALLBB, FMLALLBT, FMLALLTB, FMLALLTT (vector): 8-bit floating-point multiply-add to single-precision (vector).

FMLS (by element): Floating-point fused multiply-subtract from accumulator (by element).

FMLS (vector): Floating-point fused multiply-subtract from accumulator (vector).

FMLSL, FMLSL2 (by element): Floating-point fused multiply-subtract long from accumulator (by element).

FMLSL, FMLSL2 (vector): Floating-point fused multiply-subtract long from accumulator (vector).

FMMLA (non-widening): Half-precision matrix multiply-accumulate.

FMMLA (widening, 8-bit floating-point to half-precision): 8-bit floating-point matrix multiply-accumulate to half-precision.

FMMLA (widening, 8-bit floating-point to single-precision): 8-bit floating-point matrix multiply-accumulate to single-precision.

FMMLA (widening, half-precision to single-precision): Half-precision matrix multiply-accumulate to single-precision.

FMOV (general): Floating-point move to or from general-purpose register without conversion.

FMOV (register): Floating-point move register without conversion.

FMOV (scalar, immediate): Floating-point move immediate (scalar).

FMOV (vector, immediate): Floating-point move immediate (vector).

FMSUB: Floating-point fused multiply-subtract (scalar).

FMUL (by element): Floating-point multiply (by element).

FMUL (scalar): Floating-point multiply (scalar).

FMUL (vector): Floating-point multiply (vector).

FMULX: Floating-point multiply extended.

FMULX (by element): Floating-point multiply extended (by element).

FNEG (scalar): Floating-point negate (scalar).

FNEG (vector): Floating-point negate (vector).

FNMADD: Floating-point negated fused multiply-add (scalar).

FNMSUB: Floating-point negated fused multiply-subtract (scalar).

FNMUL (scalar): Floating-point multiply-negate (scalar).

FRECPE: Floating-point reciprocal estimate.

FRECPS: Floating-point reciprocal step.

FRECPX: Floating-point reciprocal exponent (scalar).

FRINT32X (scalar): Floating-point round to 32-bit integer, using current rounding mode (scalar).

FRINT32X (vector): Floating-point round to 32-bit integer, using current rounding mode (vector).

FRINT32Z (scalar): Floating-point round to 32-bit integer toward zero (scalar).

FRINT32Z (vector): Floating-point round to 32-bit integer toward zero (vector).

FRINT64X (scalar): Floating-point round to 64-bit integer, using current rounding mode (scalar).

FRINT64X (vector): Floating-point round to 64-bit integer, using current rounding mode (vector).

FRINT64Z (scalar): Floating-point round to 64-bit integer toward zero (scalar).

FRINT64Z (vector): Floating-point round to 64-bit integer toward zero (vector).

FRINTA (scalar): Floating-point round to integral, to nearest with ties to away (scalar).

FRINTA (vector): Floating-point round to integral, to nearest with ties to away (vector).

FRINTI (scalar): Floating-point round to integral, using current rounding mode (scalar).

FRINTI (vector): Floating-point round to integral, using current rounding mode (vector).

FRINTM (scalar): Floating-point round to integral, toward minus infinity (scalar).

FRINTM (vector): Floating-point round to integral, toward minus infinity (vector).

FRINTN (scalar): Floating-point round to integral, to nearest with ties to even (scalar).

FRINTN (vector): Floating-point round to integral, to nearest with ties to even (vector).

FRINTP (scalar): Floating-point round to integral, toward plus infinity (scalar).

FRINTP (vector): Floating-point round to integral, toward plus infinity (vector).

FRINTX (scalar): Floating-point round to integral exact, using current rounding mode (scalar).

FRINTX (vector): Floating-point round to integral exact, using current rounding mode (vector).

FRINTZ (scalar): Floating-point round to integral, toward zero (scalar).

FRINTZ (vector): Floating-point round to integral, toward zero (vector).

FRSQRTE: Floating-point reciprocal square root estimate.

FRSQRTS: Floating-point reciprocal square root step.

FSCALE: Floating-point adjust exponent by vector.

FSQRT (scalar): Floating-point square root (scalar).

FSQRT (vector): Floating-point square root (vector).

FSUB (scalar): Floating-point subtract (scalar).

FSUB (vector): Floating-point subtract (vector).

INS (element): Insert vector element from another vector element.

INS (general): Insert vector element from general-purpose register.

LD1 (multiple structures): Load multiple single-element structures to one, two, three, or four registers.

LD1 (single structure): Load one single-element structure to one lane of one register.

LD1R: Load one single-element structure and replicate to all lanes (of one register).

LD2 (multiple structures): Load multiple 2-element structures to two registers.

LD2 (single structure): Load single 2-element structure to one lane of two registers.

LD2R: Load single 2-element structure and replicate to all lanes of two registers.

LD3 (multiple structures): Load multiple 3-element structures to three registers.

LD3 (single structure): Load single 3-element structure to one lane of three registers.

LD3R: Load single 3-element structure and replicate to all lanes of three registers.

LD4 (multiple structures): Load multiple 4-element structures to four registers.

LD4 (single structure): Load single 4-element structure to one lane of four registers.

LD4R: Load single 4-element structure and replicate to all lanes of four registers.

LDAP1 (SIMD&FP): Load-acquire RCpc one single-element structure to one lane of one register.

LDAPUR (SIMD&FP): Load-acquire RCpc SIMD&FP register (unscaled offset).

LDBFADD, LDBFADDA, LDBFADDAL, LDBFADDL: Atomic BFloat16 add.

LDBFMAX, LDBFMAXA, LDBFMAXAL, LDBFMAXL: Atomic BFloat16 maximum.

LDBFMAXNM, LDBFMAXNMA, LDBFMAXNMAL, LDBFMAXNML: Atomic BFloat16 maximum number.

LDBFMIN, LDBFMINA, LDBFMINAL, LDBFMINL: Atomic BFloat16 minimum.

LDBFMINNM, LDBFMINNMA, LDBFMINNMAL, LDBFMINNML: Atomic BFloat16 minimum number.

LDFADD, LDFADDA, LDFADDAL, LDFADDL: Atomic floating-point add.

LDFMAX, LDFMAXA, LDFMAXAL, LDFMAXL: Atomic floating-point maximum.

LDFMAXNM, LDFMAXNMA, LDFMAXNMAL, LDFMAXNML: Atomic floating-point maximum number.

LDFMIN, LDFMINA, LDFMINAL, LDFMINL: Atomic floating-point minimum.

LDFMINNM, LDFMINNMA, LDFMINNMAL, LDFMINNML: Atomic floating-point minimum number.

LDNP (SIMD&FP): Load pair of SIMD&FP registers, with non-temporal hint.

LDP (SIMD&FP): Load pair of SIMD&FP registers.

LDR (immediate, SIMD&FP): Load SIMD&FP register (immediate offset).

LDR (literal, SIMD&FP): Load SIMD&FP register (PC-relative literal).

LDR (register, SIMD&FP): Load SIMD&FP register (register offset).

LDTNP (SIMD&FP): Load unprivileged pair of SIMD&FP registers, with non-temporal hint.

LDTP (SIMD&FP): Load unprivileged pair of SIMD&FP registers.

LDUR (SIMD&FP): Load SIMD&FP register (unscaled offset).

LUTI2: Lookup table read with 2-bit indices.

LUTI4: Lookup table read with 4-bit indices.

MLA (by element): Multiply-add to accumulator (vector, by element).

MLA (vector): Multiply-add to accumulator (vector).

MLS (by element): Multiply-subtract from accumulator (vector, by element).

MLS (vector): Multiply-subtract from accumulator (vector).

MOV (element): Move vector element to another vector element: an alias of INS (element).

MOV (from general): Move general-purpose register to a vector element: an alias of INS (general).

MOV (scalar): Move vector element to scalar: an alias of DUP (element).

MOV (to general): Move vector element to general-purpose register: an alias of UMOV.

MOV (vector): Move vector: an alias of ORR (vector, register).

MOVI: Move immediate (vector).

MUL (by element): Multiply (vector, by element).

MUL (vector): Multiply (vector).

MVN: Bitwise NOT (vector): an alias of NOT.

MVNI: Move inverted immediate (vector).

NEG (vector): Negate (vector).

NOT: Bitwise NOT (vector).

ORN (vector): Bitwise inclusive OR NOT (vector).

ORR (vector, immediate): Bitwise inclusive OR (vector, immediate).

ORR (vector, register): Bitwise inclusive OR (vector, register).

PMUL: Polynomial multiply.

PMULL, PMULL2: Polynomial multiply long.

RADDHN, RADDHN2: Rounding add returning high narrow.

RAX1: Rotate and exclusive-OR.

RBIT (vector): Reverse bit order (vector).

REV16 (vector): Reverse elements in 16-bit halfwords (vector).

REV32 (vector): Reverse elements in 32-bit words (vector).

REV64: Reverse elements in 64-bit doublewords (vector).

RSHRN, RSHRN2: Rounding shift right narrow (immediate).

RSUBHN, RSUBHN2: Rounding subtract returning high narrow.

SABA: Signed absolute difference and accumulate.

SABAL, SABAL2: Signed absolute difference and accumulate long.

SABD: Signed absolute difference.

SABDL, SABDL2: Signed absolute difference long.

SADALP: Signed add and accumulate long pairwise.

SADDL, SADDL2: Signed add long (vector).

SADDLP: Signed add long pairwise.

SADDLV: Signed add long across vector.

SADDW, SADDW2: Signed add wide.

SCVTF (scalar SIMD&FP): Signed integer convert to floating-point (scalar SIMD&FP).

SCVTF (scalar, fixed-point): Signed fixed-point convert to floating-point (scalar).

SCVTF (scalar, integer): Signed integer convert to floating-point (scalar).

SCVTF (vector, fixed-point): Signed fixed-point convert to floating-point (vector).

SCVTF (vector, integer): Signed integer convert to floating-point (vector).

SDOT (by element): Dot product signed arithmetic (vector, by element).

SDOT (vector): Dot product signed arithmetic (vector).

SHA1C: SHA1 hash update (choose).

SHA1H: SHA1 fixed rotate.

SHA1M: SHA1 hash update (majority).

SHA1P: SHA1 hash update (parity).

SHA1SU0: SHA1 schedule update 0.

SHA1SU1: SHA1 schedule update 1.

SHA256H: SHA-256 hash update (part 1).

SHA256H2: SHA-256 hash update (part 2).

SHA256SU0: SHA-256 schedule update 0.

SHA256SU1: SHA-256 schedule update 1.

SHA512H: SHA-512 hash update part 1.

SHA512H2: SHA-512 hash update part 2.

SHA512SU0: SHA-512 schedule update 0.

SHA512SU1: SHA-512 schedule update 1.

SHADD: Signed halving add.

SHL: Shift left (immediate).

SHLL, SHLL2: Shift left long (by element size).

SHRN, SHRN2: Shift right narrow (immediate).

SHSUB: Signed halving subtract.

SLI: Shift left and insert (immediate).

SM3PARTW1: SM3PARTW1.

SM3PARTW2: SM3PARTW2.

SM3SS1: SM3SS1.

SM3TT1A: SM3TT1A.

SM3TT1B: SM3TT1B.

SM3TT2A: SM3TT2A.

SM3TT2B: SM3TT2B.

SM4E: SM4 encode.

SM4EKEY: SM4 key.

SMAX: Signed maximum (vector).

SMAXP: Signed maximum pairwise.

SMAXV: Signed maximum across vector.

SMIN: Signed minimum (vector).

SMINP: Signed minimum pairwise.

SMINV: Signed minimum across vector.

SMLAL, SMLAL2 (by element): Signed multiply-add long (vector, by element).

SMLAL, SMLAL2 (vector): Signed multiply-add long (vector).

SMLSL, SMLSL2 (by element): Signed multiply-subtract long (vector, by element).

SMLSL, SMLSL2 (vector): Signed multiply-subtract long (vector).

SMMLA (vector): Signed 8-bit integer matrix multiply-accumulate to 32-bit integer (vector).

SMOV: Signed move vector element to general-purpose register.

SMULL, SMULL2 (by element): Signed multiply long (vector, by element).

SMULL, SMULL2 (vector): Signed multiply long (vector).

SQABS: Signed saturating absolute value.

SQADD: Signed saturating add.

SQDMLAL, SQDMLAL2 (by element): Signed saturating doubling multiply-add long (by element).

SQDMLAL, SQDMLAL2 (vector): Signed saturating doubling multiply-add long.

SQDMLSL, SQDMLSL2 (by element): Signed saturating doubling multiply-subtract long (by element).

SQDMLSL, SQDMLSL2 (vector): Signed saturating doubling multiply-subtract long.

SQDMULH (by element): Signed saturating doubling multiply returning high half (by element).

SQDMULH (vector): Signed saturating doubling multiply returning high half.

SQDMULL, SQDMULL2 (by element): Signed saturating doubling multiply long (by element).

SQDMULL, SQDMULL2 (vector): Signed saturating doubling multiply long.

SQNEG: Signed saturating negate.

SQRDMLAH (by element): Signed saturating rounding doubling multiply accumulate returning high half (by element).

SQRDMLAH (vector): Signed saturating rounding doubling multiply accumulate returning high half (vector).

SQRDMLSH (by element): Signed saturating rounding doubling multiply subtract returning high half (by element).

SQRDMLSH (vector): Signed saturating rounding doubling multiply subtract returning high half (vector).

SQRDMULH (by element): Signed saturating rounding doubling multiply returning high half (by element).

SQRDMULH (vector): Signed saturating rounding doubling multiply returning high half.

SQRSHL: Signed saturating rounding shift left (register).

SQRSHRN, SQRSHRN2: Signed saturating rounded shift right narrow (immediate).

SQRSHRUN, SQRSHRUN2: Signed saturating rounded shift right unsigned narrow (immediate).

SQSHL (immediate): Signed saturating shift left (immediate).

SQSHL (register): Signed saturating shift left (register).

SQSHLU: Signed saturating shift left unsigned (immediate).

SQSHRN, SQSHRN2: Signed saturating shift right narrow (immediate).

SQSHRUN, SQSHRUN2: Signed saturating shift right unsigned narrow (immediate).

SQSUB: Signed saturating subtract.

SQXTN, SQXTN2: Signed saturating extract narrow.

SQXTUN, SQXTUN2: Signed saturating extract unsigned narrow.

SRHADD: Signed rounding halving add.

SRI: Shift right and insert (immediate).

SRSHL: Signed rounding shift left (register).

SRSHR: Signed rounding shift right (immediate).

SRSRA: Signed rounding shift right and accumulate (immediate).

SSHL: Signed shift left (register).

SSHLL, SSHLL2: Signed shift left long (immediate).

SSHR: Signed shift right (immediate).

SSRA: Signed shift right and accumulate (immediate).

SSUBL, SSUBL2: Signed subtract long.

SSUBW, SSUBW2: Signed subtract wide.

ST1 (multiple structures): Store multiple single-element structures from one, two, three, or four registers.

ST1 (single structure): Store a single-element structure from one lane of one register.

ST2 (multiple structures): Store multiple 2-element structures from two registers.

ST2 (single structure): Store single 2-element structure from one lane of two registers.

ST3 (multiple structures): Store multiple 3-element structures from three registers.

ST3 (single structure): Store single 3-element structure from one lane of three registers.

ST4 (multiple structures): Store multiple 4-element structures from four registers.

ST4 (single structure): Store single 4-element structure from one lane of four registers.

STBFADD, STBFADDL: Atomic BFloat16 floating-point add, without return.

STBFMAX, STBFMAXL: Atomic BFloat16 floating-point maximum, without return.

STBFMAXNM, STBFMAXNML: Atomic BFloat16 floating-point maximum number, without return.

STBFMIN, STBFMINL: Atomic BFloat16 floating-point minimum, without return.

STBFMINNM, STBFMINNML: Atomic BFloat16 floating-point minimum number, without return.

STFADD, STFADDL: Atomic floating-point add, without return.

STFMAX, STFMAXL: Atomic floating-point maximum, without return.

STFMAXNM, STFMAXNML: Atomic floating-point maximum number, without return.

STFMIN, STFMINL: Atomic floating-point minimum, without return.

STFMINNM, STFMINNML: Atomic floating-point minimum number, without return.

STL1 (SIMD&FP): Store-release a single-element structure from one lane of one register.

STLUR (SIMD&FP): Store-release SIMD&FP register (unscaled offset).

STNP (SIMD&FP): Store pair of SIMD&FP registers, with non-temporal hint.

STP (SIMD&FP): Store pair of SIMD&FP registers.

STR (immediate, SIMD&FP): Store SIMD&FP register (immediate offset).

STR (register, SIMD&FP): Store SIMD&FP register (register offset).

STTNP (SIMD&FP): Store unprivileged pair of SIMD&FP registers, with non-temporal hint.

STTP (SIMD&FP): Store unprivileged pair of SIMD&FP registers.

STUR (SIMD&FP): Store SIMD&FP register (unscaled offset).

SUB (vector): Subtract (vector).

SUBHN, SUBHN2: Subtract returning high narrow.

SUDOT (by element): Dot product with signed and unsigned integers (vector, by element).

SUQADD: Signed saturating accumulate of unsigned value.

SXTL, SXTL2: Signed extend long: an alias of SSHLL, SSHLL2.

TBL: Table vector lookup.

TBX: Table vector lookup extension.

TRN1: Transpose vectors (primary).

TRN2: Transpose vectors (secondary).

UABA: Unsigned absolute difference and accumulate.

UABAL, UABAL2: Unsigned absolute difference and accumulate long.

UABD: Unsigned absolute difference (vector).

UABDL, UABDL2: Unsigned absolute difference long.

UADALP: Unsigned add and accumulate long pairwise.

UADDL, UADDL2: Unsigned add long (vector).

UADDLP: Unsigned add long pairwise.

UADDLV: Unsigned sum long across vector.

UADDW, UADDW2: Unsigned add wide.

UCVTF (scalar SIMD&FP): Unsigned integer convert to floating-point (scalar SIMD&FP).

UCVTF (scalar, fixed-point): Unsigned fixed-point convert to floating-point (scalar).

UCVTF (scalar, integer): Unsigned integer convert to floating-point (scalar).

UCVTF (vector, fixed-point): Unsigned fixed-point convert to floating-point (vector).

UCVTF (vector, integer): Unsigned integer convert to floating-point (vector).

UDOT (by element): Dot product unsigned arithmetic (vector, by element).

UDOT (vector): Dot product unsigned arithmetic (vector).

UHADD: Unsigned halving add.

UHSUB: Unsigned halving subtract.

UMAX: Unsigned maximum (vector).

UMAXP: Unsigned maximum pairwise.

UMAXV: Unsigned maximum across vector.

UMIN: Unsigned minimum (vector).

UMINP: Unsigned minimum pairwise.

UMINV: Unsigned minimum across vector.

UMLAL, UMLAL2 (by element): Unsigned multiply-add long (vector, by element).

UMLAL, UMLAL2 (vector): Unsigned multiply-add long (vector).

UMLSL, UMLSL2 (by element): Unsigned multiply-subtract long (vector, by element).

UMLSL, UMLSL2 (vector): Unsigned multiply-subtract long (vector).

UMMLA (vector): Unsigned 8-bit integer matrix multiply-accumulate to 32-bit integer (vector).

UMOV: Unsigned move vector element to general-purpose register.

UMULL, UMULL2 (by element): Unsigned multiply long (vector, by element).

UMULL, UMULL2 (vector): Unsigned multiply long (vector).

UQADD: Unsigned saturating add.

UQRSHL: Unsigned saturating rounding shift left (register).

UQRSHRN, UQRSHRN2: Unsigned saturating rounded shift right narrow (immediate).

UQSHL (immediate): Unsigned saturating shift left (immediate).

UQSHL (register): Unsigned saturating shift left (register).

UQSHRN, UQSHRN2: Unsigned saturating shift right narrow (immediate).

UQSUB: Unsigned saturating subtract.

UQXTN, UQXTN2: Unsigned saturating extract narrow.

URECPE: Unsigned reciprocal estimate.

URHADD: Unsigned rounding halving add.

URSHL: Unsigned rounding shift left (register).

URSHR: Unsigned rounding shift right (immediate).

URSQRTE: Unsigned reciprocal square root estimate.

URSRA: Unsigned rounding shift right and accumulate (immediate).

USDOT (by element): Dot product with unsigned and signed integers (vector, by element).

USDOT (vector): Dot product with unsigned and signed integers (vector).

USHL: Unsigned shift left (register).

USHLL, USHLL2: Unsigned shift left long (immediate).

USHR: Unsigned shift right (immediate).

USMMLA (vector): Unsigned and signed 8-bit integer matrix multiply-accumulate to 32-bit integer (vector).

USQADD: Unsigned saturating accumulate of signed value.

USRA: Unsigned shift right and accumulate (immediate).

USUBL, USUBL2: Unsigned subtract long.

USUBW, USUBW2: Unsigned subtract wide.

UXTL, UXTL2: Unsigned extend long: an alias of USHLL, USHLL2.

UZP1: Unzip vectors (primary).

UZP2: Unzip vectors (secondary).

XAR: Exclusive-OR and rotate.

XTN, XTN2: Extract narrow.

ZIP1: Zip vectors (primary).

ZIP2: Zip vectors (secondary).

ABS

Absolute value (vector)

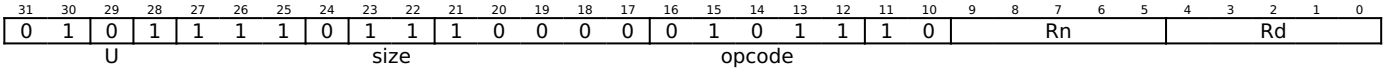
This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register. If the value in an element of the source vector is the most negative value, the result for that element is the same as the value in that element of the source vector.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

(FEAT_AdvSIMD)



Encoding

```
ABS D<d>, D<n>
```

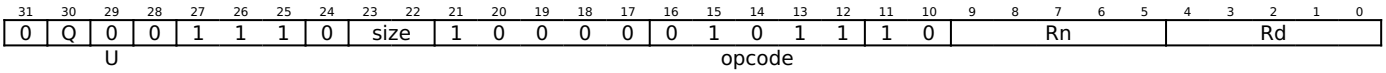
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);

let esize : integer{} = 8 << UInt(size);
let datasize : integer{} = esize;
let elements : integer = 1;
```

Vector

(FEAT_AdvSIMD)



Encoding

```
ABS <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if size::Q == '110' then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);

let esize : integer{} = 8 << UInt(size);
let datasize : integer{} = 64 << UInt(Q);
let elements : integer = datasize DIV esize;
```

Assembler Symbols

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in “(size :: Q)”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(datasize) = V{}(n);
var result : bits(datasize);
var element : integer;

for e = 0 to elements-1 do
    element = SInt(operand[e*:esize]);
    element = Abs(element);
    result[e*:esize] = element[esize-1:0];
end;

V{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

ADD (vector)

Add (vector)

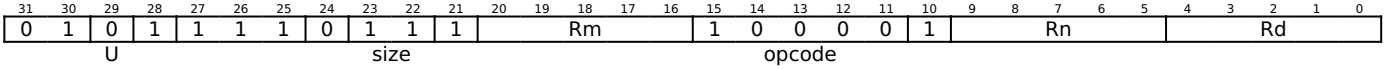
This instruction adds corresponding elements in the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

(FEAT_AdvSIMD)



Encoding

```
ADD D<d>, D<n>, D<m>
```

Decode for this encoding

ADDHN, ADDHN2

Add returning high narrow

This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

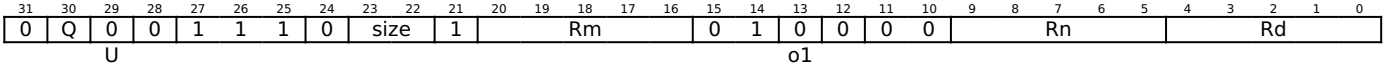
The results are truncated. For rounded results, see *RADDHN*.

The ADDHN instruction writes the vector to the lower half of the destination register and clears the upper half. The ADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

(FEAT_AdvSIMD)



Encoding

```
ADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if size == '11' then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);

let esize : integer{} = 8 << UInt(size);
let datasize : integer{} = 64;
let part : integer = UInt(Q);
let elements : integer = datasize DIV esize;
let round : boolean = FALSE;
```

Assembler Symbols

2 — Is the second and upper half specifier. If present, it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<Vd> — Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> — Is an arrangement specifier, encoded in “(size :: Q)”:

size	Q	<Tb>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	x	RESERVED

<Vn> — Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> — Is an arrangement specifier, encoded in “size”:

size	<Ta>
00	8H
01	4S
10	2D
11	RESERVED

<Vm> — Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(2*datasize) = V{}(n);
let operand2 : bits(2*datasize) = V{}(m);
var result : bits(datasize);
var element1 : integer;
var element2 : integer;
var sum : integer;

for e = 0 to elements-1 do
    element1 = UInt(operand1[e*:(2*esize)]);
    element2 = UInt(operand2[e*:(2*esize)]);
    sum = element1 + element2;
    sum = RShr(sum, esize, round);
    result[e*:esize] = sum[esize-1:0];
end;

Vpart{datasize}(d, part) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

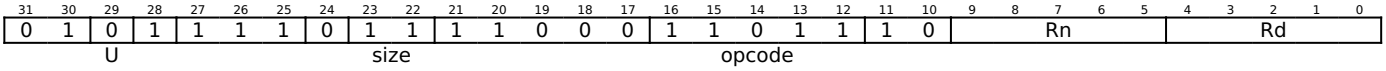
ADDP (scalar)

Add pair of elements (scalar)

This instruction adds two vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD

(FEAT_AdvSIMD)



Encoding

```
ADDP D<d>, <Vn>.2D
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let esize : integer{} = 64;
let datasize : integer{} = 128;
```

Assembler Symbols

<d>	Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(datasize) = V{}(n);
V{esize}(d) = IntReduce{esize, datasize}(ReduceOp_ADD, operand);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

ADDP (vector)

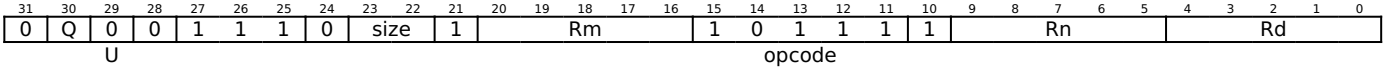
Add pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

(FEAT_AdvSIMD)



Encoding

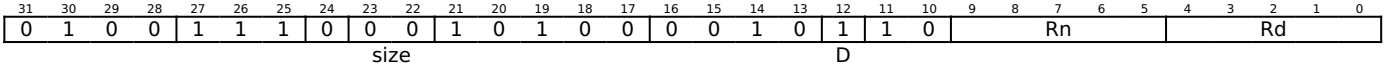
AESD

AES single round decryption

This instruction reads a 16-byte state array from the first source vector, together with a round key from the second source vector. The state array undergoes a single round of the AddRoundKey(), InvShiftRows(), and InvSubBytes() transformations in accordance with the AES standard. The updated state array is destructively placed in the first source vector.

Advanced SIMD

(FEAT_AES)



Encoding

```
AESD <Vd>.16B, <Vn>.16B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AES) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Vd>	Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.
<Vn>	Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();

let operand1 : bits(128) = V{}(d);
let operand2 : bits(128) = V{}(n);
var result : bits(128) = operand1 XOR operand2;
result = AESInvShiftRows(result);
V{128}(d) = AESInvSubBytes(result);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

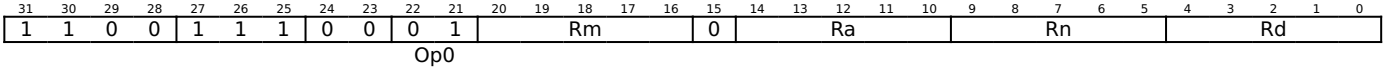
BCAX

Bit clear and exclusive-OR

This instruction performs a bitwise AND between the 128-bit vector in a source SIMD&FP register and the complement of the vector in another source SIMD&FP register, then performs a bitwise exclusive-OR between the resulting vector and the vector in a third source SIMD&FP register, and writes the result to the destination SIMD&FP register.

Advanced SIMD

(FEAT_SHA3)



Encoding

```
BCAX <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA3) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

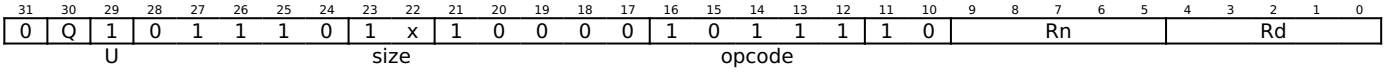
BF1CVTL, BF1CVTL2, BF2CVTL, BF2CVTL2

8-bit floating-point convert to BFloat16 (vector)

This instruction converts each 8-bit floating-point element from the lower or upper half of the source vector to BFloat16 while downscaling the value, and places the results in the 16-bit elements of the destination vector. BF1CVTL and BF2CVTL convert the elements from the lower half of the source vector while scaling the values by $2^{-UInt(FPMR.LSCALE[5:0])}$ and $2^{-UInt(FPMR.LSCALE2[5:0])}$, respectively. BF1CVTL2 and BF2CVTL2 convert the elements from the upper half of the source vector while scaling the values by $2^{-UInt(FPMR.LSCALE[5:0])}$ and $2^{-UInt(FPMR.LSCALE2[5:0])}$, respectively. The 8-bit floating-point encoding format for BF1CVTL and BF1CVTL2 is selected by FPMR.F8S1. The 8-bit floating-point encoding format for BF2CVTL and BF2CVTL2 is selected by FPMR.F8S2.

Advanced SIMD

(FEAT_FP8)



Encoding for the BF1CVTL{2} variant

Applies when `(size == 10)`

```
BF1CVTL{2} <Vd>.8H, <Vn>.<Ta>
```

Encoding for the BF2CVTL{2} variant

Applies when `(size == 11)`

```
BF2CVTL{2} <Vd>.8H, <Vn>.<Ta>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP8) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let part : integer = UInt(Q);
let elements : integer = 64 DIV 8;
let issrc2 : boolean = size == '11';
```

Assembler Symbols

2 — Is the second and upper half specifier. If present, it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<Vd> — Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> — Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> — Is an arrangement specifier, encoded in “Q”:

Q	<Ta>
0	8B
1	16B

Operation

```
CheckFPMREnabled(); AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(64) = Vpart{}(n, part);
var result : bits(128);

for e = 0 to elements-1 do
    result[e*:16] = FP8ConvertBF(operand[e*:8], issrc2, FPCR(), FPMR());
end;

V{128}(d) = result;
```

BFCVT

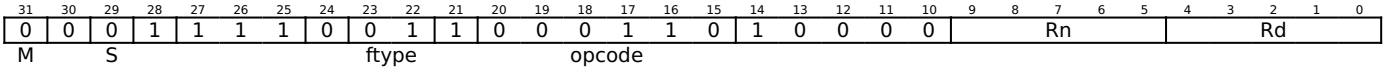
Single-precision convert to BFloat16 (scalar)

This instruction converts the single-precision floating-point value in the 32-bit SIMD&FP source register to BFloat16 format and writes the result in the 16-bit SIMD&FP destination register.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

Single-precision to BFloat16

(FEAT_BF16)



Encoding

```
BFCVT <Hd>, <Sn>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_BF16) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
```

Assembler Symbols

<Hd>	Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64_CheckFPEnabled();

let operand : bits(32) = V{}(n);
let merge : boolean = IsMerging(FPCR());
var result : bits(128) = if merge then V{128}(d) else Zeros{128};

result[0+:16] = FPConvertBF(operand, FPCR());
V{128}(d) = result;
```

BFCVTN, BFCVTN2

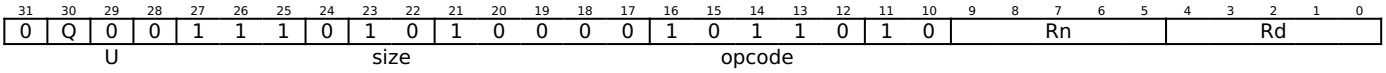
Single-precision convert to BFloat16 (vector)

This instruction reads each single-precision element in the SIMD&FP source vector, converts each value to BFloat16 format, and writes the results in the lower or upper half of the SIMD&FP destination vector. The result elements are half the width of the source elements.

The `BFCVTN` instruction writes the half-width results to the lower half of the 128-bit SIMD&FP destination vector and clears the upper half to zero. The `BFCVTN2` instruction writes the results to the upper half of the 128-bit SIMD&FP destination vector without affecting the lower half.

Vector single-precision to BFloat16

(FEAT_BF16)



Encoding

```
BFCVTN{2} <Vd>.<Ta>, <Vn>.4S
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_BF16) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let part : integer = UInt(Q);
let elements : integer = 64 DIV 16;
```

Assembler Symbols

2 — Is the second and upper half specifier. If present, it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<Vd> — Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> — Is an arrangement specifier, encoded in “Q”:

Q	<Ta>
0	4H
1	8H

<Vn> — Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(128) = V{}(n);
var result : bits(64);

for e = 0 to elements-1 do
    result[e*:16] = FPConvertBF(operand[e*:32], FPCR());
end;

Vpart{64}(d, part) = result;
```

BFDOT (by element)

BFloat16 dot product to single-precision (vector, by element)

This instruction delimits the source vectors into pairs of BFloat16 elements. The BFloat16 pair within the second source vector is specified using an immediate index. The index range is from 0 to 3 inclusive.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Honors FPCR.AH when generating a default NaN result, otherwise disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

- Performs a fused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

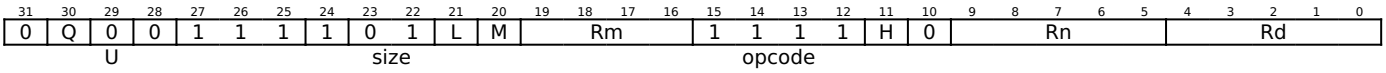
Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

Advanced SIMD

(FEAT_BF16)



Encoding

```
BFDOT <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.2H[<index>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_BF16) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let m : integer = UInt(M::Rm);
let d : integer = UInt(Rd);
let i : integer = UInt(H::L);
let datasize : integer{} = 64 << UInt(Q);
let elements : integer = datasize DIV 32;
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in “Q”:

Q	<Ta>
0	2S
1	4S

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in “Q”:

Q	<Tb>
0	4H
1	8H

<Vm> Is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

<index> Is the immediate index of a pair of 16-bit elements in the range 0 to 3, encoded in the "H:L" fields.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(datasize) = V{}(n);
let operand2 : bits(128) = V{}(m);
let operand3 : bits(datasize) = V{}(d);
var result : bits(datasize);

for e = 0 to elements-1 do
    let elt1_a : bits(16) = operand1[(2 * e + 0)*:16];
    let elt1_b : bits(16) = operand1[(2 * e + 1)*:16];
    let elt2_a : bits(16) = operand2[(2 * i + 0)*:16];
    let elt2_b : bits(16) = operand2[(2 * i + 1)*:16];

    let sum : bits(32) = operand3[e*:32];
    result[e*:32] = BFDotAdd(sum, elt1_a, elt1_b, elt2_a, elt2_b, FPCR());
end;

V{datasize}(d) = result;
```

BFDOT (vector)

BFloat16 dot product to single-precision (vector)

This instruction delimits the source vectors into pairs of BFloat16 elements.
If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the source vectors. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the source vectors.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Honors FPCR.AH when generating a default NaN result, otherwise disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

- Performs a fused sum-of-products of each pair of adjacent BFloat16 elements in the source vectors. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the source vectors.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

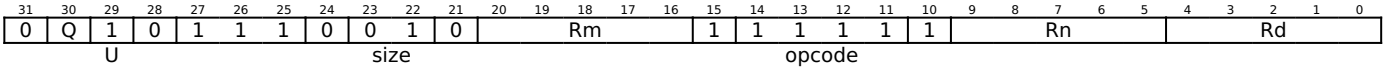
Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

Advanced SIMD

(FEAT_BF16)



Encoding

```
BFDOT <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_BF16) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 64 << UInt(Q);
let elements : integer = datasize DIV 32;
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in “Q”:

Q	<Ta>
0	2S
1	4S

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in “Q”:

Q	<Tb>
0	4H
1	8H

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(datasize) = V{}(n);
let operand2 : bits(datasize) = V{}(m);
let operand3 : bits(datasize) = V{}(d);
var result : bits(datasize);

for e = 0 to elements-1 do
    let elt1_a : bits(16) = operand1[(2 * e + 0)*:16];
    let elt1_b : bits(16) = operand1[(2 * e + 1)*:16];
    let elt2_a : bits(16) = operand2[(2 * e + 0)*:16];
    let elt2_b : bits(16) = operand2[(2 * e + 1)*:16];

    let sum : bits(32) = operand3[e*:32];
    result[e*:32] = BFDotAdd(sum, elt1_a, elt1_b, elt2_a, elt2_b, FPCR());
end;

V{datasize}(d) = result;

BFMLALB, BFMLALT (by element)

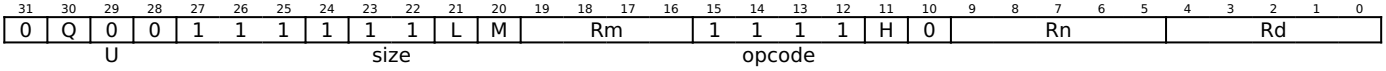
BFloat16 multiply-add to single-precision (by element)

This instruction widens the even-numbered (bottom) or odd-numbered (top) 16-bit elements in the first source vector, and the indexed element in the second source vector from Bfloat16 to single-precision format. The instruction then multiplies and adds these values without intermediate rounding to single-precision elements of the destination vector that overlap with the corresponding BFloat16 elements in the first source vector.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

Vector

(FEAT_BF16)



Encoding

BFMMLA (widening)

BFloat16 matrix multiply-accumulate to single-precision

This instruction multiplies the 2x4 matrix of BFloat16 values held in the first source vector by the 4x2 matrix of BFloat16 values in the second source vector.
If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Calculates the intermediate single-precision results as a sum of two unfused sum-of-products using two pairs of adjacent BFloat16 values from each of the source vectors, and then rounds the results before accumulation into the 2x2 matrix of single-precision results in the destination vector. This is equivalent to accumulating a 4-way dot product per destination element.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Honors FPCR.AH when generating a default NaN result, otherwise disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, this instruction:

- Calculates the intermediate single-precision results as a sum of two fused sum-of-products using two pairs of adjacent BFloat16 values from each of the source vectors, and then rounds the results before accumulation into the 2x2 matrix of single-precision results in the destination vector. This is equivalent to accumulating a 4-way dot product per destination element.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

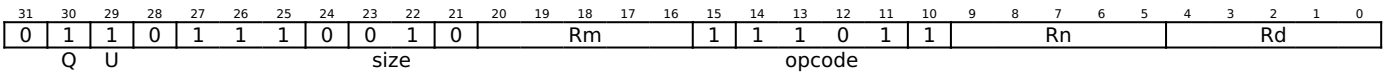
Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

Advanced SIMD

(FEAT_BF16)



Encoding

```
BFMMLA <Vd>.4S, <Vn>.8H, <Vm>.8H
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_BF16) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
```

Assembler Symbols

<Vd>	Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let op1 : bits(128) = V{}(n);
let op2 : bits(128) = V{}(m);
let acc : bits(128) = V{}(d);

V{128}(d) = BFMatMulAddH(acc, op1, op2, FPCR());
```

Operational information

Arm expects that the BFMMLA instruction will deliver a peak BFloat16 multiply throughput that is at least as high as can be achieved using two BFDOT (vector) instructions, with a goal that it should have significantly higher throughput.

BIC (vector, immediate)

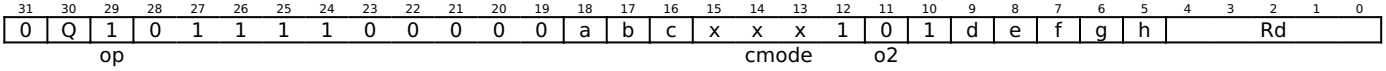
Bitwise bit clear (vector, immediate)

This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise AND between each result and the complement of an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Shifted immediate

(FEAT_AdvSIMD)



Encoding for the 16-bit variant

Applies when `(cmode == 10x1)`

```
BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Encoding for the 32-bit variant

Applies when `(cmode == 0xx1)`

```
BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let rd : integer = UInt(Rd);
let datasize : integer{} = 64 << UInt(Q);
let imm64 : bits(64) = AdvSIMDExpandImm(op, cmode, a::b::c::d::e::f::g::h);
let imm : bits(datasize) = Replicate{}(imm64);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP register, encoded in the "Rd" field.

<T> For the "16-bit" variant: is an arrangement specifier, encoded in “Q”:

Q	<T>
0	4H
1	8H

For the "32-bit" variant: is an arrangement specifier, encoded in “Q”:

Q	<T>
0	2S
1	4S

<imm8> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount> For the "16-bit" variant: is the shift amount encoded in “cmode[1]”:

cmode[1]	<amount>
0	0
1	8

defaulting to 0 if LSL is omitted.

For the "32-bit" variant: is the shift amount encoded in “cmode[2:1]”:

cmode[2:1]	<amount>
00	0
01	8
10	16
11	24

defaulting to 0 if LSL is omitted.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(datasize) = V{}(rd);
V{datasize}(rd) = operand AND NOT(imm);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

CMEQ (register)

Compare bitwise equal (vector)

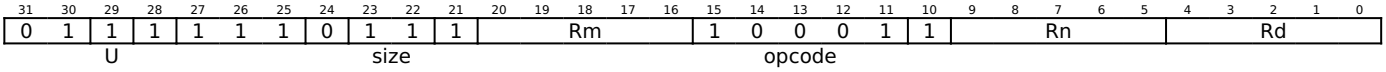
This instruction compares each vector element from the first source SIMD&FP register with the corresponding vector element from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

(FEAT_AdvSIMD)



Encoding

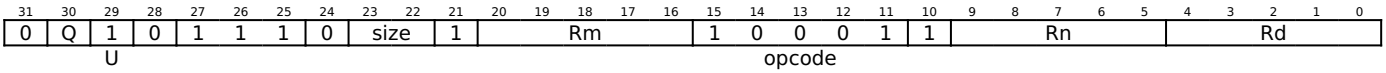
```
CMEQ D<d>, D<n>, D<m>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let esize : integer{} = 8 << UInt(size);
let datasize : integer{} = esize;
let elements : integer = 1;
```

Vector

(FEAT_AdvSIMD)



Encoding

```
CMEQ <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if size::Q == '110' then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let esize : integer{} = 8 << UInt(size);
let datasize : integer{} = 64 << UInt(Q);
let elements : integer = datasize DIV esize;
```

Assembler Symbols

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in “(size :: Q)”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(datasize) = V{}(n);
let operand2 : bits(datasize) = V{}(m);
var result : bits(datasize);
var element1 : bits(esize);
var element2 : bits(esize);

for e = 0 to elements-1 do
    element1 = operand1[e*:esize];
    element2 = operand2[e*:esize];
    result[e*:esize] = if element1 == element2 then Ones{esize} else Zeros{esize};
end;

V{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

CMLT (zero)

Compare signed less than zero (vector)

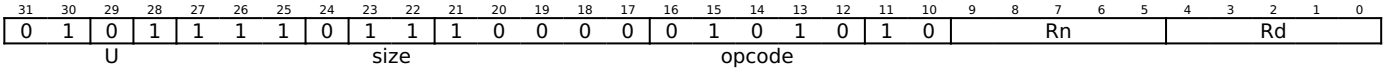
This instruction reads each vector element in the source SIMD&FP register and if the signed integer value is less than zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

(FEAT_AdvSIMD)



Encoding

```
CMLT D<d>, D<n>, #0
```

Decode for this encoding

```

CMTST

Compare bitwise test bits nonzero (vector)

This instruction reads each vector element in the first source SIMD&FP register, performs an AND with the corresponding vector element in the second source SIMD&FP register, and if the result is not zero, sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

CNT

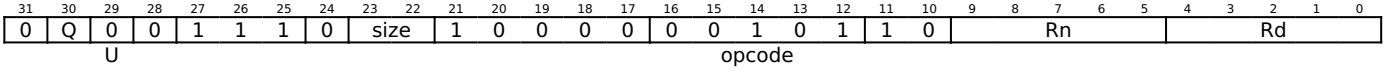
Population count per byte

This instruction determines the number of bits that have a value of one in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector

(FEAT_AdvSIMD)



Encoding

```
CNT <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if size != '00' then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);

let esize : integer{} = 8;
let datasize : integer{} = 64 << UInt(Q);
let elements : integer = datasize DIV 8;
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in “(size :: Q)”:

size	Q	<T>
00	0	8B
00	1	16B
01	x	RESERVED
1x	x	RESERVED

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(datasize) = V{}(n);
var result : bits(datasize);

for e = 0 to elements-1 do
    let count : integer = BitCount(operand[e*:esize]);
    result[e*:esize] = count[esize-1:0];
end;
V{datasize}(d) = result;
```

Operational information

DUP (element)

Duplicate vector element to vector or scalar

This instruction duplicates the vector element at the specified element index in the source SIMD&FP register into a scalar or each element in a vector, and writes the result to the destination SIMD&FP register.

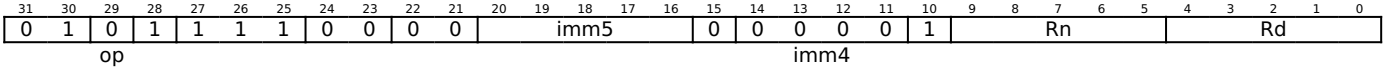
Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (scalar).

It has encodings from 2 classes: Scalar and Vector

Scalar

(FEAT_AdvSIMD)



Encoding

```
DUP <V><d>, <Vn>.<T>[<index>]
```

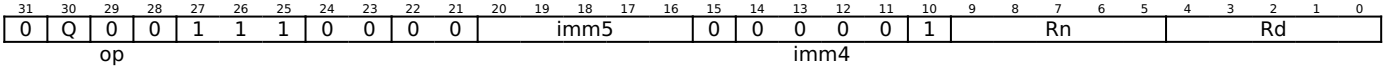
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = LowestSetBitNZ(imm5[3:0]);

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let index : integer = UInt(imm5[4:size+1]);
let idxdsize : integer{} = 64 << UInt(imm5[4]);
let esize : integer{} = 8 << size;
let datasize : integer{} = esize;
let elements : integer = 1;
```

Vector

(FEAT_AdvSIMD)



Encoding

```
DUP <Vd>.<T>, <Vn>.<Ts>[<index>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF); end;
if imm5 == 'x1000' && Q == '0' then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = LowestSetBitNZ(imm5[3:0]);

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let index : integer = UInt(imm5[4:size+1]);
let idxdsize : integer{} = 64 << UInt(imm5[4]);
let esize : integer{} = 8 << size;
let datasize : integer{} = 64 << UInt(Q);
let elements : integer = datasize DIV esize;
```

Assembler Symbols

<V> Is the destination width specifier, encoded in “imm5”:

imm5	<V>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> For the "Scalar" variant: is the element width specifier, encoded in “imm5”:

imm5	<T>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

For the "Vector" variant: is an arrangement specifier, encoded in “(imm5 :: Q)”:

imm5	Q	<T>
x0000	x	RESERVED
xxxx1	0	8B
xxxx1	1	16B
xxx10	0	4H
xxx10	1	8H
xx100	0	2S
xx100	1	4S
x1000	0	RESERVED
x1000	1	2D

<index> Is the element index encoded in “imm5”:

imm5	<index>
x0000	RESERVED
xxxx1	UInt(imm5[4:1])
xxx10	UInt(imm5[4:2])
xx100	UInt(imm5[4:3])
x1000	UInt(imm5[4])

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ts> Is an element size specifier, encoded in “imm5”:

DUP (general)

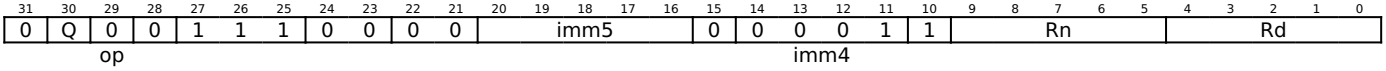
Duplicate general-purpose register to vector

This instruction duplicates the contents of the source general-purpose register into a scalar or each element in a vector, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD

(FEAT_AdvSIMD)



Encoding

```
DUP <Vd>.<T>, <R><n>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF); end;
if imm5 == 'x1000' && Q == '0' then EndOfDecode(Decode_UNDEF); end;
let size : integer{} = LowestSetBitNZ(imm5[3:0]);

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);

// imm5[4:size+1] is IGNORED
let esize : integer{} = 8 << size;
let datasize : integer{} = 64 << UInt(Q);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in “(imm5 :: Q)”:

imm5	Q	<T>
x0000	x	RESERVED
xxxx1	0	8B
xxxx1	1	16B
xxx10	0	4H
xxx10	1	8H
xx100	0	2S
xx100	1	4S
x1000	0	RESERVED
x1000	1	2D

<R> Is the width specifier for the general-purpose source register, encoded in “imm5”:

imm5	<R>
x0000	RESERVED
xxxx1	W
xxx10	W
xx100	W
x1000	X

Unspecified bits in "imm5" are ignored but should be set to zero by an assembler.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let element : bits(esize) = X{esize}(n);
let elements : integer = datasize DIV esize;
var result : bits(datasize);

for e = 0 to elements-1 do
    result[e*:esize] = element;
end;
V{datasize}(d) = result;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

EOR (vector)

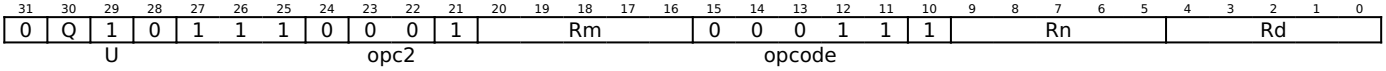
Bitwise exclusive-OR (vector)

This instruction performs a bitwise exclusive-OR between the first source SIMD&FP register and the second source SIMD&FP register, and places the result in the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

(FEAT_AdvSIMD)



Encoding

```
EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let datasize : integer{} = 64 << UInt(Q);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in “Q”:

Q	<T>
0	8B
1	16B

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();

let operand1 : bits(datasize) = V{}(m);
let operand2 : bits(datasize) = Zeros{};
let operand3 : bits(datasize) = Ones{};
let operand4 : bits(datasize) = V{}(n);
V{datasize}(d) = operand1 XOR ((operand2 XOR operand4) AND operand3);
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

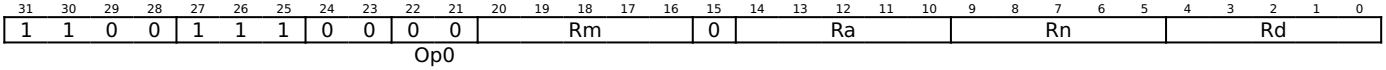
EOR3

Three-way exclusive-OR

This instruction performs a three-way exclusive-OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Advanced SIMD

(FEAT_SHA3)



Encoding

```
EOR3 <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA3) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let a : integer{} = UInt(Ra);
```

Assembler Symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Va>	Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();

let operand1 : bits(128) = V{}(m);
let operand2 : bits(128) = V{}(n);
let operand3 : bits(128) = V{}(a);
V{128}(d) = operand2 XOR operand1 XOR operand3;
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

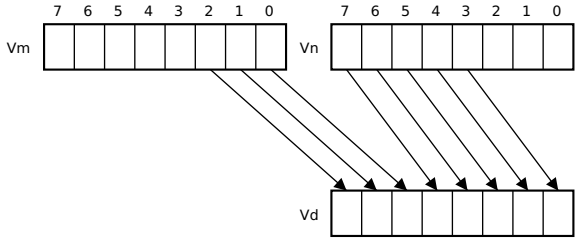
EXT

Extract vector from pair of vectors

This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

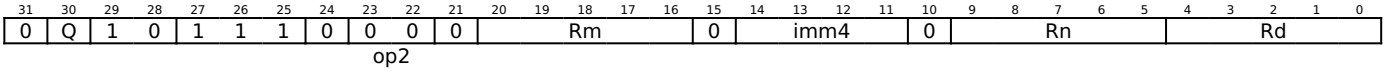
The following figure shows an example of the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.



Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD

(FEAT_AdvSIMD)



Encoding

```
EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if Q == '0' && imm4[3] == '1' then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);

let datasize : integer{} = 64 << UInt(Q);
let position : integer{} = 8 * UInt(imm4);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in “Q”:

Q	<T>
0	8B
1	16B

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<index> Is the lowest numbered byte element to be extracted, encoded in “(Q :: imm4)”:

Q	imm4[3]	<index>
0	0	UInt(imm4[2:0])
0	1	RESERVED
1	x	UInt(imm4)

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let hi : bits(datasize) = V{datasize}(m);
let lo : bits(datasize) = V{datasize}(n);
let concat : bits(datasize*2) = hi :: lo;

V{datasize}(d) = concat[(position+datasize)-1:position];
```

Operational information

This instruction is a data-independent-time instruction as described in *About PSTATE.DIT*.

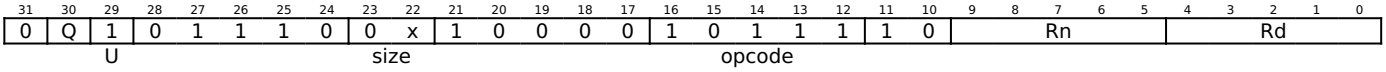
F1CVTL, F1CVTL2, F2CVTL, F2CVTL2

8-bit floating-point convert to half-precision (vector)

This instruction converts each 8-bit floating-point element from the lower or upper half of the source vector to half-precision while downscaling the value, and places the results in the 16-bit elements of the destination vector. `F1CVTL` and `F2CVTL` convert the elements from the lower half of the source vector while scaling the values by $2^{-UInt(FPMR.LSCALE[3:0])}$ and $2^{-UInt(FPMR.LSCALE2[3:0])}$, respectively. `F1CVTL2` and `F2CVTL2` convert the elements from the upper half of the source vector while scaling the values by $2^{-UInt(FPMR.LSCALE[3:0])}$ and $2^{-UInt(FPMR.LSCALE2[3:0])}$, respectively. The 8-bit floating-point encoding format for `F1CVTL` and `F1CVTL2` is selected by FPMR.F8S1. The 8-bit floating-point encoding format for `F2CVTL` and `F2CVTL2` is selected by FPMR.F8S2.

Advanced SIMD

(FEAT_FP8)



Encoding for the F1CVTL{2} variant

Applies when `(size == 00)`

```
F1CVTL{2} <Vd>.8H, <Vn>.<Ta>
```

Encoding for the F2CVTL{2} variant

Applies when `(size == 01)`

```
F2CVTL{2} <Vd>.8H, <Vn>.<Ta>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP8) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let d : integer = UInt(Rd);
let part : integer = UInt(Q);
let elements : integer = 64 DIV 8;
let issrc2 : boolean = size == '01';
```

Assembler Symbols

2 — Is the second and upper half specifier. If present, it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<Vd> — Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> — Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> — Is an arrangement specifier, encoded in “Q”:

Q	<Ta>
0	8B
1	16B

Operation

```
CheckFPMREnabled(); AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(64) = Vpart{}(n, part);
var result : bits(128);

for e = 0 to elements-1 do
    result[e*:16] = FP8ConvertFP(operand[e*:8], issrc2, FPCR(), FPMR());
end;

V{128}(d) = result;
```

FABD

Floating-point absolute difference (vector)

This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

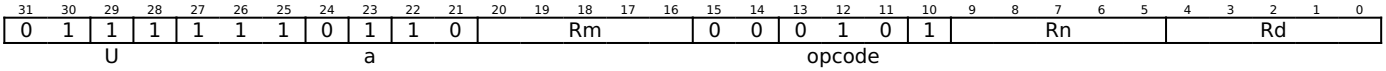
This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision , Scalar single-precision and double-precision , Vector half-precision and Vector single-precision and double-precision

Scalar half-precision

(FEAT_AdvSIMD && FEAT_FP16)



Encoding

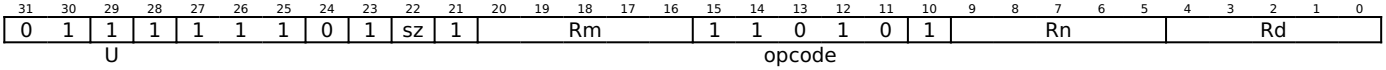
```
FABD <Hd>, <Hn>, <Hm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) || !IsFeatureImplemented(FEAT_FP16) then
    EndOfDecode(Decode_UNDEF);
end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let esize : integer{} = 16;
let datasize : integer{} = esize;
let elements : integer = 1;
```

Scalar single-precision and double-precision

(FEAT_AdvSIMD)



Encoding

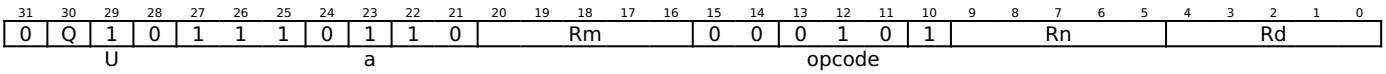
```
FABD <V><d>, <V><n>, <V><m>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let esize : integer{} = 32 << UInt(sz);
let datasize : integer{} = esize;
let elements : integer = 1;
```

Vector half-precision

(FEAT_AdvSIMD && FEAT_FP16)



Encoding

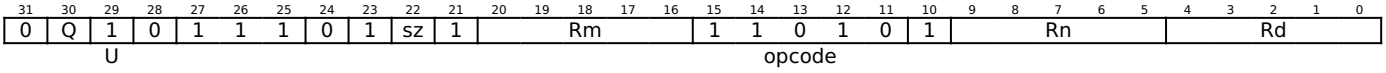
```
FABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) || !IsFeatureImplemented(FEAT_FP16) then
    EndOfDecode(Decode_UNDEF);
end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let esize : integer{} = 16;
let datasize : integer{} = 64 << UInt(Q);
let elements : integer = datasize DIV esize;
```

Vector single-precision and double-precision

(FEAT_AdvSIMD)



Encoding

```
FABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if sz::Q == '10' then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let esize : integer{} = 32 << UInt(sz);
let datasize : integer{} = 64 << UInt(Q);
let elements : integer = datasize DIV esize;
```

Assembler Symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<V> Is a width specifier, encoded in “sz”:

sz	<V>
0	S
1	D

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the "Vector half-precision" variant: is an arrangement specifier, encoded in “Q”:

Q	<T>
0	4H
1	8H

For the "Vector single-precision and double-precision" variant: is an arrangement specifier, encoded in “(sz :: Q)”:

sz	Q	<T>
0	0	2S
0	1	4S
1	0	RESERVED
1	1	2D

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(datasize) = V{}(n);
let operand2 : bits(datasize) = V{}(m);

var element1 : bits(esize);
var element2 : bits(esize);
let merge : boolean = elements == 1 && IsMerging(FPCR());
var result : bits(128) = if merge then V{128}(n) else Zeros{128};

for e = 0 to elements-1 do
    element1 = operand1[e*:esize];
    element2 = operand2[e*:esize];
    let diff : bits(esize) = FPSub{}(element1, element2, FPCR());
    result[e*:esize] = FPAbs{esize}(diff, FPCR());
end;

V{128}(d) = result;
```

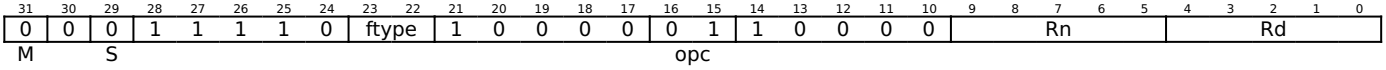
FABS (scalar)

Floating-point absolute value (scalar)

This instruction calculates the absolute value in the SIMD&FP source register and writes the result to the SIMD&FP destination register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision variant (FEAT_FP16)

Applies when `(ftype == 11)`

```
FABS <Hd>, <Hn>
```

Encoding for the Single-precision variant (FEAT_FP)

Applies when `(ftype == 00)`

```
FABS <Sd>, <Sn>
```

Encoding for the Double-precision variant (FEAT_FP)

Applies when `(ftype == 01)`

```
FABS <Dd>, <Dn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF); end;
if ftype == '10' then EndOfDecode(Decode_UNDEF); end;
if ftype == '11' && !IsFeatureImplemented(FEAT_FP16) then EndOfDecode(Decode_UNDEF); end;

let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);

let esize : integer{} = 8 << UInt(ftype XOR '10');
```

Assembler Symbols

<Hd>	Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn>	Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

FACGE

Floating-point absolute compare greater than or equal (vector)

This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.
